An example of these delays was given by W. C. Leland of the Lincoln Motors Co., in which he mentions that the making of heavier bearings in the connecting rod called for a change of 165 jigs and fixtures. The difficulty of getting these was accentuated by the crowded condition of tool shops and the necessity of using inexperienced tool makers in many of these shops.

The Lelands employed the best tool makers it was possible to obtain in the country and yet many of these tools were rejected. They had to be made within 1/1000 in. accuracy and when they arrived they were 7/1000, 8/1000 and often 9/1000 out of accuracy. The Lincoln company had to make over many of these jigs and fixtures and had to build over practically every jig and fixture with its own workmen in the factory. At one time it had 83 different factories in the country, extending from Maine to Ohio and including Iowa and Illinois, manufacturing tools. This work was greatly increased by changes in the crankshaft and connecting rods as well as others in the propeller hub.

Unfortunately the public fails to even think of the enormous work of changing all of these jigs and fixtures and when it criticises it fails to realize the many steps in quantity production and the time and money required in getting a factory tooled and jigged for production manufacture.

### Increase in Power Brought Trouble

There were many other troubles with the Liberty engine, most of which might be traced to the increase in power from the original 330 to the present 440 hp. There were difficulties with radiation, lubrication and carburetion. The original crankshaft was not an oil pressure one and the changing to an oil pressure system carried many changes with it.

As soon as the manufacture of different parts of the engine was passed on to the different manufacturers, many changes in parts were suggested by these manufacturers in order to make production possible.

The Aircraft Production Board, according to the evidence, heeded a great many of these changes, which naturally caused delay, but in the end worked for production.

One of these might be cited: The manufacture of the forged steel cylinders by the Ford company from tubing instead of from a solid forging as was used in the experimental engine. The use of the forging has proved to be one of the great manufacturing achievements in connection with our aircraft program.

There were many other delays resulting from a failure of quick communication between Europe and America and at this writing it would seem that a much more comprehensive mission should have been sent to study the aircraft situation in June of 1917 than was sent.

Here again it was human to err and unquestionably there was not a single person in America at that time to grasp the magnitude of the work sufficiently to select an adequate mission for the work. As a result, the necessary engineering information was not supplied promptly enough from Europe and the program lagged. This may be the reason why the engine program after all, although one of the biggest, outstripped that of ordnance and equipment for the combat planes.

### Expected Too Much of Engine

There may be a just criticism in the fact that too much of the engineering talent connected with the Aircraft Production Board was sewed up in the design and development of the Liberty engine. Today it looks as if an error were committed in expecting the Liberty engine to fill the complete gamut of airplane requirement.

Perhaps it was an error to think that this engine made with four, six, eight or twelve cylinders would perform any phase of combat work at the front.

From the various hearings in the sub-committee report, the reader is apt to reach the conclusion that part of the program was held back pending the development of the Liberty engine and the proving of its suitability for all phases of work. For example, the development of heavy bombing planes does not seem to have made the progress it should and seems to have been delayed until the suitability of the Liberty engine for this work was decided upon.

This seems to be borne out by the report which says that in October, 1917, we had the necessary facilities to build the Caproni bombing plane and that as early as January, 1918, we had expert Caproni engineers in this country ready to proceed with the manufacture of this plane.

### Delay in Transmitting Orders

Although so qualified to go ahead, it was not until Sept. 1 of this year that the first Caproni was constructed. As long ago as the summer of 1917 the Standard Aircraft Co., Elizabeth, N. J., was instructed to have its factory in readiness to build these Caproni machines, but nothing definite was decided upon.

As long ago as October, 1917, at Paris, France, the manufacture of the Caproni was taken up between our Mission and Italy and the apparent decision to go ahead was given; but notwithstanding this it was

Col E. A. Deeds

Charles W. Nash

W. C. Potter

January, 1918, before the Standard Aircraft company was given a verbal order to go ahead with 1400 of these machines, and at the date of the report no official order confirming the verbal order seems to have been given.

Lack of decision in connection with the production of this plane was further indicated by the fact that in April, 1918, the Fisher Body Co., Detroit, was given a contract to complete 250 of these planes, which contract was later canceled.

The report fails to bring out just why there was so much vacillation in connection with this Caproni program, but undoubtedly it was due to the lack of certain information or some policy connected with the work. For example, on Sept. 15, 1917, the Curtiss airplane corporation was given a verbal contract to build 1500 Capronis, which contract was confirmed in October. The Curtiss company appears never to have obtained the necessary information to go ahead and the contract was canceled later.

## Automobile Industry Unjustly Censured in Senate Report

Failure of Government to Give "Go Ahead" Order Has Held Up Production—There Has Been No Profiteering, as Thinly Suggested in Report—Industry Has Done Well

By J. Edward Schipper

**D**ETROIT, Aug. 27—*Special to AUTOMOTIVE INDUSTRIES*—In the eyes of the automobile industry the report of the Senate Committee on aircraft matters places the Government in the light of having bitten the hand that fed it. It is regarded as regrettable from every standpoint and particularly as a very bad preface to the coming Liberty Loan campaign when every ounce of public confidence will be needed.

Were the report true in spirit, it would not have caused the dismay in the industry that it has. "Where," it is asked, "would the government have turned in its efforts to find men of experience in engine production if it had not turned to the auto-

mobile industry?" Yet the industry is blamed for having turned over its facilities, disrupted its tool-rooms, disorganized its production schedules to enthusiastically and patriotically take up the manufacture of a product recognized to be the most difficult in the world to manufacture.

In spite of all difficulties the end of a year of work, Sept. 5, 1918, will see 20,000 airplane engines manufactured in this country. Of this 6000 are Liberty engines and the balance are made up of the Hispano-Suiza, Curtiss OX, Hall-Scott, Gnome and LeRhône types. The manufacturing schedule will total 3000 Liberty engines a month by the end of September. In addition to these there will be 1000 Curtiss and

600 Hispano-Suiza engines per month. Were it not for the automobile industry, what percentage of these would have been made?

At this very time, when the ways should be all cleared for the production of airplanes up to the very limit of productive ability, the full capacity of our plants is not being utilized. The natural tendency to stop action until the completion of an investigation is directly responsible for this.

The Fisher Body Co., with a capacity of twenty planes per day, has never been able to get "go ahead" orders enough to keep its plant going full swing.

The Ford Motor Co. could have been much further ahead in its production schedule than it now is if orders had been released.

The automobile industry was ready and willing but vacillating policies prevented the throwing of full productive effort into airplane production.

The now-historic \$640,000,000 appropriation and the references to it in the report come in for bitter comment by some of the industry who were active in framing the original policy in regard to airplane matters. It is claimed that this appropriation was worked out by the army itself on an estimated production of 22,500 planes. There never was any prediction or expectation that this number was to be ready by July 1. The appropriation was worked out by General Pulloy and his technical board at the time of the framing of the appropriation bill. Of this number it was planned to order 5000 in Europe, 7000 were to be training planes and the remainder fighting planes. No one seems to be able to find any foundation in fact for the much-cited statement that this country would manufacture 22,500 planes by July 1.

What was predicted and what could have been done was to have reached a production of 1000 planes per month by July 1. Dayton-Wright alone could have reached 100 per day with 70 per cent spares or nearly 170.

Fisher could have been started, to say nothing of Curtiss and other plants scattered throughout the country. With investigations coming on, those vested with the power to order were naturally afraid to move with the result that men in the AUTOMOTIVE INDUSTRY WENT AHEAD AND ORDERED MATERIAL IN ADVANCE OF RELEASE ON ORDERS SO THAT PRODUCTION WOULD NOT SUFFER ON ACCOUNT OF THE DELAY. Yet, the automobile industry is accused in the report of being responsible for delay.

The bitterest pill of all to swallow is the thinly veiled accusation of profiteering. This is particularly true of the Liberty engine program. When the time came to fix a price on the Liberty engine there was nothing to go on except what had been paid for foreign airplane engines. These had been sold from

Col. Sidney Walden

\$20 to \$30 per horsepower. The Liberty engine with 450 hp. would have been estimated at \$9,000 at the lowest in accordance with foreign costs. Rolling White of Cleveland and Henry May, vice-president of the Pierce-Arrow, were called into consultation on the matter and at the suggestion of the Secretary of War estimated the cost. The figure placed by them was \$6,000 for the twelve-cylinder engine.

AFTER ENTERING INTO PRODUCTION THE MANUFACTURERS THEMSELVES WITHOUT DISSENT CUT THE ALLOWED COST FIGURE TO \$5,000. On this a flat profit of 12½ per cent was allowed.

Most absurd of all, in the eyes of the industry, is the claim in the report that we should have

gone ahead on quantity production of foreign types. Anyone who has had experience with past experiments in this field can see what this would have led to. The experience of the Wright-Martin company in manufacturing the Hispano-Suiza engine may be referred to, for instance. On an order for 400 of these engines, it took 18 months to get into production and after entering production, 4 months to turn out the 400 engines.

The experience of the Willys-Overland with the Sunbeam is another typical example. This company received in June, 1917, an order to build 1000 Sunbeams. Due to changes and imperfections in the drawings, but six motors had been completed in May, 1918. The airplanes of England, which has a production schedule of some 2800 per month, are produced in approximately 300 plants of various sizes scattered all over the kingdom. It is doubted whether any one of these plants could produce a complete set of detail construction drawings for any one plane. They are hand-made and far removed from the manufacturing proposition that American methods call for.

#### Handley-Page Delays

When the Handley-Page made its long flights and attracted attention to its flying qualities, it was decided to build that type of plane in this country. The Handley-Page company offered at a fancy price to supply its drawings and data for manufacture. Arrangements were then made with the British government over the heads of all commercial parties for the free exchange of manufacturing licenses for the period of the war and the drawings of the Handley-Page were sent over. A great number of dies were made by concerns like the Mullins Steel Boat, when a new set of drawings incorporating improvements were sent over and the whole set of dies had to be scrapped. This occurred three times before a proper set of dies for the metal fittings of this plane could be made. This all helped to spend some of the

appropriation and showed that we could not rely on foreign practice to help us much.

Even taking the best of foreign practice as represented in the Rolls-Royce engine. With 10,000 employees this company turns out 50 of these engines a week. The recommendation that we build this engine which does not equal in performance the Liberty and which falls short of its production facilities by the ratio of about 1 to 7, will hardly be carried out. The Rolls-Royce parts ordered by England to be made in this country are not being delivered now. With this difficulty in making the parts, it is easy to see what would have been encountered in

making the first engine. A total of 6000 Liberty engines in the first year looks large in comparison.

**ENGLAND'S DESIRE FOR 20,000 LIBERTY ENGINES IMMEDIATELY IS ADDITIONAL INDORSEMENT IF ANY BE NECESSARY.**

That the Senate Committee listened too much to small manufacturers who although they had engaged to some extent in the airplane business, were absolutely ignorant of war requirements and certainly of quantity production, is the belief of many. It is upon evidence of this kind, in the belief of these people, that the committee based its statements re-

(Continued on page 358)

## Uncertainty Still Exists in Aircraft Program on Planes

### We Are Still Adapting Discarded European Types—Foreign Engineer's Reports Not Accepted—Bristol Plane May Be Re-Adopted

By ALLEN SINSHEIMER

**W**ASHINGTON, Aug. 27—The vague assurances regarding the immediate and future plans of our air program as told in the recent Senate report, combined with perplexing rumors of our activities in connection with Allied airplanes, still leave considerable uncertainty in the public mind, although the report has done much to clarify public opinion with regard to the earlier aircraft activities. The Senate's publication of the testimony of the witnesses in this matter has also helped to clear the atmosphere.

Rumors are current that a mistake was made in the selection of the SE 5 airplane which we have adapted from the British. It is said that the SE 5 was discarded by England in September, 1917, for the SE 5A, which has a higher speed and all around better performance. The SE 5A in turn, while still in use, was discarded for the Sopwith Camel which, in turn, has been discarded for the Sopwith Dolphin, which is now being replaced by the Sopwith Snipe. Each of these machines in turn has been regarded as superior to the preceding one by the British experts. Hence the public is asking why we have adopted the SE 5 long discarded by England.

#### Why the Bristol Failed

The failure of the Bristol airplane also arouses speculation. There is really no question about this. The American authorities simply took the Bristol airplane, which was designed by English experts for the 190 h.p. Rolls-Royce engine, which weighed 660 lb., and attempted to use it with the 450 h.p. Liberty engine weighing more than 950 lb. The excess weight and surplus power were not suited to the plane. Furthermore, the construction of the Liberty engine is entirely different from the Rolls-Royce and it occupied a greater width of space in the body

of the plane, which also had not entered into the calculations of its original construction. Consequently there was no surprise on the part of foreign experts when they learned that the planes fell away from the fuselage and that serious accidents had resulted. The attempts to use heavier fabric in this plane to counteract the heavier weight were not sufficient in them.

#### To Re-Adopt Bristol

And now after a year of experiment costly both in money and lives, comes the report that the American Government is again going to adopt the Bristol airplane equipped this time with the Hispano-Suiza engine. But strange to say, instead of adopting the latest Bristol type which is equipped with a 300 h.p. Hispano-Suiza, we are adopting the Bristol type used 2 years ago in England and long since discarded.

In his testimony before the Senate Military Affairs Committee, Major General Kenly spoke of the SE 5 as a two-passenger machine similar to the French Spad. He led Senator Reed to remark that it was strange that we had no single-seater. The SE 5 is really, according to authentic information, not a two-seater plane. It is a single-seated machine and differs in appearance, performance and horsepower considerably from the Spad.

An example of the lack of thorough co-operation between the experts and our authorities is shown in a recent instance where the most skilled foreign experts were called to this country to investigate and report on our training activities. They made an exhausted study and filed the report. This report has never reached the hand of Major General Kenly for whom it was intended, and up to this time the work performed by the men called from abroad has been wasted.

Foreign experts in this country are, of course, obligated by their position to refrain from criticism of our activities, but it is not difficult to learn that they are more or less discouraged and disgusted. Stories are told of how designs are brought in to them daily for their approval and even after they are O.K'd are never used. Some of these designs, it is said, are foolish and a waste of time, embodying many unnecessary practices, such as sport and racing lines similar to designs of racing automobiles. Others embody exceedingly valuable principles, but since they are never converted into airplanes are merely wasted. It is also said that many of the engineers waste their time drawing these "beautiful" designs without ever taking into consideration the necessary calculations and dimensions. •

Another example of our delay is found in the Caproni plane which Italy is turning out at the rate of several hundred a month. We have one Caproni plane finished. We might have had 2000 by this time had the authorities placed the orders a year ago. And now after months of delay and experiments and final completion of one machine authentic reports are to the effect that the orders just placed for Caproni machines have been cancelled and the entire Caproni program abolished. Following the experiments, tests and the excellent reports this action has created bewilderment and astonishment in the minds of both the public and the foreign air authorities. Up to this time no reason has been given for this action.

#### Aircraft Bomb Uncertainty

Still another instance of the apparent lack of co-operation is shown in our air bomb construction. The Allies discarded the single fuse bomb two years ago for the bomb with an instantaneous fuse at one end and a time fuse at the other. They also limited the production of the small 20-lb. bombs and increased on the 260-lb. and 500-lb. bombs. Up to a few weeks ago, according to reports here, the American authorities were concentrat-

ing their efforts on a single fuse 20-lb. bomb. Apparently there has been some protest, as it is now said that investigations are being held regarding the advisability of building the larger and two-fuse bombs.

"Too much desire to change," "too many engineers with individual preferences," "too many authorities" and "too little regard for foreign engineering practices" are said to be the principal causes for our airplane failure by those foreign experts who could be induced to express an opinion. They complain that when a type of airplane, such, for example, as the Caproni, is brought to this country, everyone of several hundred engineers has different opinions for changing the design, with the result that much time is wasted and that frequently harmful practices are incorporated.

#### DeHaviland Changes

Another example is that of the DeHaviland 4 as made in this country and regarding which many officers testified before the Senate Committee telling that it was too dangerous to fly. This machine as made in this country differs so radically from the British machine that it is difficult to realize that it is an adaptation from it. The original DeHaviland 4 is recognized as one of the most efficient airplanes used at the front. In fact, the entire DeHaviland line of airplanes are recognized as being among the best produced. It is said that no DeHaviland has been a failure. Yet our engineers so completely changed the DeHaviland 4 that it is reported to be a failure in this country. It is said that they have reduced its efficiency 66 2/3 per cent by adding unnecessary structural and material equipment.

The testimony of the witnesses as made public by the Senate Military Affairs Committee, including more than 1200 pages of statements, shows that an ambitious program is still contemplated and considered possible for the coming year.

## Opinions of Aircraft Experts from Senate Report

**Kenly Tells of Conflicting Cables from Pershing — Ryan Praises Liberty Engine — DeHaviland 4 Plane Not Yet Satisfactory — Henry Ford Advocates Single Head for Airplane Work — Nash Believes We Cannot Deliver 10,000 Planes by July, 1919 — Edgar Wants More Training Fields — Caproni Contract Delays**

THE variety of impressions in the 1226 pages covering the investigation of the Sub-committee of the Committee on Military Affairs, United States Senate, indicates how even to-day this stupendous maze of aircraft necessity has not sufficiently crystallized itself so that a definite program can even to-day be outlined. The following brief extracts from the examination of a few of the 100 or more witnesses serves to indicate this.

Major General Kenly, in his statements, told that the program calls for 350 complete squadrons during the coming year. This means between 6000 and 8000 airplanes. The pilots are already being trained. More than 3000 are ready. General Kenly told the committee that at this time there are thirteen American air

squadrons in France, comprising 273 airplanes. He said that there should be 175 squadrons with approximately 3500 airplanes with the American Expeditionary Forces.

General Kenly told that General Pershing frequently sent a cablegram ordering one type of plane one day and another countermanding it the day following. He stated also that while there was no friction between the Army and the Navy, there is a strong feeling on the part of the Army that the Navy is getting more than its share. He testified that General Pershing countermanded the order for Spad production last year and confirmed the recent rumors that criticism had come from General Pershing of the DeHaviland airplanes shipped to him.

John D. Ryan, chairman of the Department of Aircraft Production, and General Kenly both approved of the centralization of aeronautical activities under one head. Stories of what they called waste of millions of dollars were told and General Kenly laid the responsibility for the early delays and failures to lack of proper organization and executive ability. The DeHaviland 4, said the general, is not yet satisfactory, but is being perfected and is likely to be successful. The DeHaviland 9, he said, will soon be in quantity production.

Mr. Ryan testified that the Liberty engine, both eight cylinder and twelve, is rapidly reaching perfection and will be widely used. General Kenly also praised the engine, but complained that the original aircraft authorities should have developed an individual airplane for the Liberty engine and used foreign airplanes temporarily, earlier in the war.

Mr. Ryan stated that Colonel Deeds of the Signal Corps and Colonel Montgomery, both of whom had been criticized in the committee's report had practically severed their connections with the Department of Aircraft Production. He said that when he took charge of this department none of the men at the head of it were experienced so far as he knew. He told that loss of time and lives and waste of millions of dollars was the result of their work. We have not built a single fighting plane up to this time, he said, because we have wasted time experimenting with a machine to fit the Liberty 12 cylinder engine. The changes ordered in the DeHaviland plane by General Pershing, he said, will make it more serviceable, useful and of greater military value. He predicted quantity production of the DeHaviland 9 by October. The Liberty engine, he said, is better than any engine on either side of the water. There will be ample spruce for airplanes according to Mr. Ryan.

W. C. Potter, who was in charge of equipment under the Signal Corps and who is now Assistant Director of Airplane Production, told that General Pershing has asked for 25,000 airplanes by July, 1919. He stated that it is possible that 18,000 or 20,000 might be delivered.

### Ford Production 100 Daily

Henry Ford told the committee that the Liberty engine was the best airplane engine that has ever been designed and that his factory would produce 100 of these engines daily in the near future. He advocated a single head to control airplane engineering, production and operation.

Charles W. Nash, president of the Nash Motor Co., and now a member of the Department of Aircraft Production in charge of engineering and production, stated that DeHaviland airplanes only could be delivered by January. He believes that delivery of 10,000 air planes by next July would be nothing short of miraculous.

The training of aviators and the surplus of pilots now awaiting airplanes was described by Colonel C. G. Edgar, who was construction head of the Signal Corps. Colonel Edgar urged the building of more training fields and stated that those now in use are seriously overcrowded. He told, for example, of Camp Kelly No. 2 at San Antonio, Texas, originally built for 2100 men and now housing 4700.

Examination of officers of the Standard Aircraft Corp. developed the fact that this company's organization was reduced by 60 per cent due to the absence of Government work. The senators spent much time with the officers of this company in questions relating to its financing.

Captain Ugo D'Annunzio of the Italian Aviation Service and formerly chief engineer of the Caproni plane,

told how he had been disappointed in finding no manufacturing facilities for the Caproni machine and how he had been led to believe that these facilities existed by various officers and manufacturers. He praised the Liberty engine. He told that he had urged the officials to give the Standard Aircraft Corp. an order for two or three hundred Caproni machines because they had already translated the drawings according to their own factory facilities and stated that this suggestion was ignored. Other Italian officials testified that practically daily the American Government aircraft authorities would change their mind regarding the production of Capronis, decided one day to build 1000 and countermanding the order the next day, deciding to change certain details of construction one day and again deciding differently the following.

Much additional testimony of this same nature showing conflicting orders and indecision was added by various manufacturers. Weaknesses of airplanes and dangerous construction was described by fliers who testified.

—

### Uncertainty Still Exists in Aircraft Program on Planes

(Continued from page 356)

garding the industry's having acted in a grasping manner toward the airplane orders.

All of the statements regarding the past do not affect the matter in hand, which is winning the war, so much as the fact that the factories now stand ready to go ahead and yet cannot get releases in sufficient quantities to keep the plants going to full capacity. Where the delay comes in, would have been a part of the report. For instance, the contract for 3000 Hispano-Suiza engines was presented by the army and cleared through the Aircraft Production Board in November, 1917. It is only within the past few weeks that "Go ahead" orders were given manufacturers on these engines. In the mean time what became of the orders? Why and where was the delay?

If anyone were to place a finger on the place where the delays have occurred it would be found to be nearly always where foreign practice entered in. The navy has gone ahead with its schedule remarkably well. It has never paid any great amount of attention to foreign development, but has followed American development straight through. It has never been possible to get foreign drawings that American shops could use. It has always been necessary to tear down the machine and measure it to make drawings that we could employ.

When all has been said, the original program of taking what we could of foreign production, but of going ahead on our own engine, the Liberty, has proven to be best. It was originally intended to make the Liberty engine in four, six, eight and twelve cylinders. We gave up all but the twelve and have now come back to the eight. Perhaps we shall return to the four and the six. This gave a range of engines that would cover every field in spite of the fact that the Senate committee points out that we have "made a mistake in trying to build an engine suitable to all purposes."

We have got to win the war. That is the final test and we need not be afraid that this country is going to fall down on its airplane program. The industry awaits the Hughes report with the feeling that it will clear up through its accuracy the vague accusations in the Senate report. In the meantime production is going ahead, and with the release of pending orders will unleash in full the productive ability of our plants. Ford is now turning out over

twenty-five Liberty engines per day, and so also are Cadillac and Lincoln Motors. The General Motors Co., in spite of the impression created by a conversation quoted in the Senate report, is doing its utmost and will soon be up to a production of fifteen per day. Perfection has not been reached, but every day irons out difficulties which appeared overwhelming a few months ago, and every day brings smoother operation of the machinery.

## Coffin Protests to Congress

**Declares Civilian Men on Aircraft Production Board Were Advisory Only and Had No Executive Powers of Any Kind—Executive Power Was Vested in Army and Navy Representatives on Board Who Determined Program**

**L**ETTERS of protest by Howard E. Coffin, former chairman of the Aircraft Production Board, were read into the Congressional Record following presentation to the Senate of the Military Affairs Committee report.

Mr. Coffin protested that neither he nor his board

had at any time any executive authority and had only been clothed with advisory powers. He stated that all contracts had been made by the various bureaus of the War and Navy Departments and that the Aircraft Board never exercised jurisdiction in these lines.

Following are the letters of protest in full:

Hon. Charles S. Thomas,  
United States Senate,  
Washington, D. C.

My Dear Senator: I am in receipt of copies of Judge Garrison's communication to you under date of July 26 and of your reply thereto under date of July 27.

The misleading publicity referred to by Judge Garrison continues to emanate from Washington at regular intervals, and has its inception in the fact that neither in the press nor in the public mind has there ever been a proper understanding of the status of the Aircraft Board or of its non-executive relation to the War and Navy departments. Even in Washington, except in the minds of those having special knowledge of the facts, there has been a tendency to ascribe to the Aircraft Board executive and administrative powers similar to those of the Shipping Board or its Emergency Fleet Corporation and capabilities of action independent of the War and Navy departments.

Much of this confusion of mind has arisen from the fact that three Army officers appointed by the Secretary of War to membership on the board and the three naval representatives appointed by the Secretary of the Navy have served in the dual capacity, namely, in an advisory and entirely non-executive role when sitting with the board, but as executive officers having full power when functioning in their capacity as bureau heads of the War and Navy departments.

I trust that, in simple justice to Mr. Howe, Mr. Thayer and myself, as the civilian members of the Aircraft Board, vested with no executive powers of any kind, and dependent for all information concerning and contact with the technical and administrative phases of the Army and Navy aircraft programs upon the duly constituted representatives and

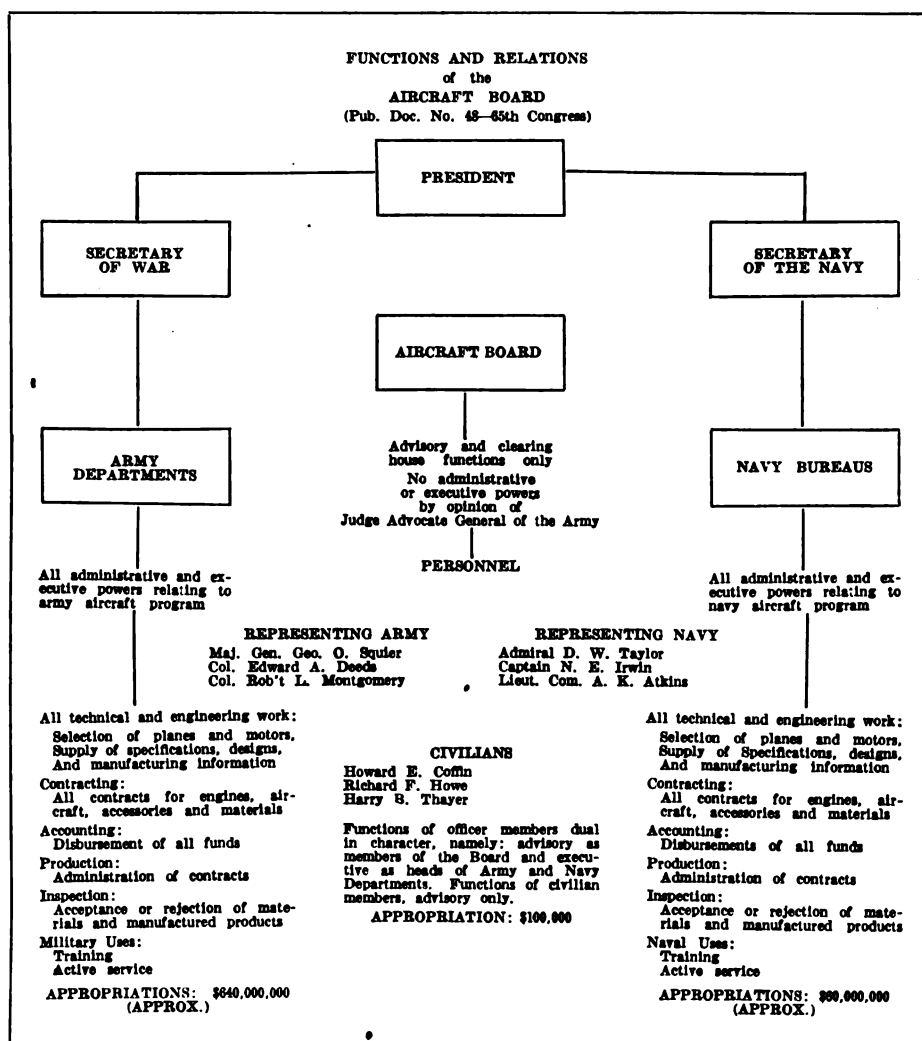

Chart to which Mr. Coffin refers and which shows the organization and personnel of the Aircraft Board

channels of these governmental departments, such a clean-cut distinction and statement of fact may be incorporated in your report as will place before the American people the true status and relations of the three organizations involved in the governmental aircraft program.

For your reference I am enclosing you herewith a chart wherein these relations are clearly set forth in accordance with the rulings of counsel of the Aircraft Board, of the office of the Judge Advocate General of the Army, and the Secretaries of War and of the Navy.

The relations of the three civilian members of the Aircraft Board and of the board itself have been exactly the same to the Navy Department as to the Army, and neither the successes nor the failures of either of these departments in technical or administrative lines can be ascribed to the civilian members of the board.

All decisions as to types of planes and engines put into production have been made by the technical organizations of the War and Navy departments, and all resolutions relating to the placing of contracts have originated within these departments before being brought before the Aircraft Board for clearance.

It has been only within these governmental departments that there has existed a sufficient knowledge as to the requirements of the air services to permit the origination of decisions and actions of this kind. Certainly Howe, Thayer and myself, as the three civilian members, did not dictate in any way in such matters.

All contracts for aircraft have been made by the duly qualified bureaus of the War and Navy departments, and the details of these contracts negotiated by the executive officers of these departments. The administration of all aircraft contracts has from the beginning lain entirely within the hands of the departments and bureaus of the Army and Navy services, and neither the civilian members of the Aircraft Board nor the board as such has ever exercised jurisdiction in these lines. It is significant in this connection that the Navy program, bearing the same relation to the Aircraft Board and its civilian members as that of the Army, and using the same forms of contract, has gone ahead and at high speed, while that of the Army has been and is still in difficulties.

Quoting from the fifth paragraph of your letter addressed to Judge Garrison, you state "that he was before the committee last January or February for something over two days, and if the program which he discussed at the time had been 10 per cent as well advanced as he then assured us it was the present investigations would have been unnecessary."

Permit me to point out to you:

1. That in these two days' hearing the subject of aviation was discussed only for a considerable portion of the first day, and that a part of the first day and the whole of the second was given over to a discussion of the general industries situation in the conduct of the war.

See page 2253 "Investigation of the

War Department Hearings before the Committee on Military Affairs of the United States Senate, Sixty-fifth Congress, Part 6, January 30 to February 2, 1918."

2. That all information given by me to the Senate committee, that portion of the first day's hearing devoted to aircraft, was, of necessity, furnished to me through the War and Navy department channels having responsibility for aircraft production, that this information was exactly the same as that being supplied by the Signal Corps of the Army to the Secretary of War and that War Department officers having the confidential military and production aircraft programs in their charge were assigned for attendance in the Senate committee rooms during my hearing in order that these reports and records might be available for reference.

3. Under the restriction of the bill creating the Aircraft Board limiting its activities to those of a non-executive nature and prohibiting the building up of any office or organization parallel or duplicating the activities of the executive bureaus of the War and Navy departments, it should be clear that the civilian members of the board were dependent entirely upon the official representatives of those executive departments for reports as to military or naval plans and progress of production. I believe it has never been within the power of the three civilian members of the board, even had the necessity been recognized, to institute a thorough-going investigation as to the truth or falsity of these War and Navy department reports made to the Board and supplied to the chairman of the board for use in the Senate committee hearing. It has seemingly required months of investigation, backed by full executive power, to enable either the Senate committee or the Judge Hughes managerial difficulties of the War Department in the carrying out of its aircraft program. It should be evident, therefore, that the civilian members of the Aircraft Board could scarcely have inaugurated an investigation of the business management and progress of the War and Navy departments' administrative bureaus, particularly in view of the fact that at the time of the Senate committee hearing of February 1 there was no realization of the necessity for such investigations.

4. In view of the figures, schedules and reports furnished by the War Department at the time of the Senate hearing, I believe my testimony before this body to have been most conservative. Permit me to call to your attention your own question addressed to Gen. Squier, to be found at the bottom of page 2134 of the Senate hearings; also to the question of Senator Wadsworth, addressed to Col. Deeds, middle of page 2153; also to statement by Chairman Chamberlain, middle of page 2157. These references indicate clearly that my statement before the committee has not been a glowing or unduly optimistic one. In my first day's hearing before you I did point out to your committee the peculiar non-executive and purely advisory relation in

which the board stood to the Army and Navy services under the creating act of October 1. I also transmitted to your committee the information furnished by the Signal Corps that it was expected that 1900 planes would have been shipped for overseas service prior to July 1. Permit me also to call to your attention the contents of the four paragraphs on page 2209 of the Senate hearing, comprising Col. Deeds' description of the manner in which the War and Navy departments' decisions as to types of planes and engines were arrived at, the method of placing contracts and the advisory or clearing-house relation of the Aircraft Board to these contractual activities.

In connection with the Senate hearing I distinctly remember stating to the committee that inasmuch as the relations of the civilian members of the board to the Army and Navy programs were indirect, it would be necessary for the committee to obtain any detailed information it might desire from the War Department officers having executive charge of the work. I believe that several such officers were subsequently called before the committee and military and production information furnished in answer to inquiries of the members of the Senate committee.

In leaving this subject of the Senate hearing in January, permit me to say that I do not believe that you or any other member of Mr. Chamberlain's committee believes that I in any way purposely misled you as to the situation. I transmitted to you gentlemen War Department information which was being embodied in reports both to the Aircraft Board and to the Secretary of War, and frankly resent any inference suggesting deception. In the records of the Aircraft Board for December and January will be found reports made to the board by the War Department representatives as to production progress. At one of the January meeting just prior to the Senate hearing the Secretary of War was himself in attendance when production reports were presented by the Signal Corps.

My statements in these matters can, should you so desire, be verified by referring them to Mr. Richard F. Howe of the International Harvester Co., the civilian member appointed to membership upon the board by President Wilson in November. Mr. Howe is now in Washington and can be reached care the Aircraft Board, of which he still remains a member.—H. E. COFFIN.

Detroit, Mich., Aug. 16, 1918.

Hon. C. S. Thomas,  
United States Senate,  
Washington, D. C.

In connection with your report as chairman of the Senate aircraft committee, may I not ask that in fairness to Messrs. Howe, Thayer and myself, as the three civilian members of the Aircraft Board, having no executive relation to the engineering, contracting, accounting, production or inspection work of the departments, you will give careful consid-

(Continued on page 391)

[Complete Text of Aircraft Report appears on page 393.]

# Benz Now Uses Aluminum Pistons

Weight of Piston Reduced 27 Per Cent and Compression Ratio Slightly Increased—Very Narrow Compression Rings a Feature

THE original Benz aircraft engines of 160 and 230 hp. had light cast iron pistons in which the piston head was slightly domed and reinforced by a perforated steel cone riveted to the head and resting with its apex on the piston pin. In February last an Aviatik biplane with 230-hp. Benz engine was brought down in which were found aluminum pistons. As these are the first aluminum pistons ever found in enemy aircraft and as they are probably the largest diameter aluminum pistons ever successfully used, details of their design and of the composition of the alloy employed should be of interest. This information has been given out by the Technical Department, Aircraft Production, British Ministry of Munitions.

## Piston Weight Reduced One-Third

The pistons weigh 4.53 lb. each without rings, which weigh 0.095 lb. each. The total weight of the complete piston, with rings and gudgeon pin set screw, is 4.91 lb., as compared with the standard cast-iron piston, which weighs 6.72 lb. The piston pins and connecting rods are of standard Benz design, as also is the rest of the engine to which these pistons were fitted. The design of the standard cast-iron Benz piston, which is fitted with a conical steel support, riveted to the inside of the piston crown, and which bears upon the center portion of the gudgeon pin through a slot cut in the connecting rod small end, is well known. Unlike the standard cast-iron piston, the domed head of the sand-cast aluminum piston is supported and strengthened by eight webs radiating from a central boss in the piston crown. The formation and shape of the webs are clearly shown in the sectional drawings.

Three cast-iron rings are fitted above the piston pin, and one scraper ring is provided below the gudgeon pin. All rings are concentric and are machine hammered on the inside. It will be noticed that the rings are all exceptionally deep in section, being 0.21 in. deep and only 0.12 in. wide vertically. The piston ring gap measured in position in a standard 230-hp. cylinder was found to be exceptionally wide, i.e., 0.076 in. As may be seen in Fig. 2, the piston pin bosses are fitted with steel bushes 0.080 in. thick. These are cast into the bosses in the usual way. The piston pins are 1.50 in. diameter, and the piston pin bosses are 2.55 in. diameter. The method of fixing the piston pin by a hexagon-headed set screw and split pin is standard Benz practice.

An annular semicircular groove 0.197 in. radius is machined on the bottom lip of the piston, as shown in the section drawing, and the inside of the skirt is machined inside up as far as the reinforcing rib of the scraper ring directly below the piston pin.

Further details of the design of these aluminum pistons are shown in the illustrations, and the chemical composition of the alloy from a metallurgical analysis carried out at R.A.E. is as follows: Copper, per cent, 6.02; zinc, per cent, 12.13; iron, per cent, 1.42; silicon, 0.31; tin, nil; nickel, nil; manganese, trace; magnesium, trace.

As the engine from which these pistons were taken was found to be too badly damaged to carry out a test, it has been impossible to ascertain the increased relative efficiency between this engine and the standard 230-hp. Benz. The compression ratio, however, is apparently slightly higher in the engines fitted with the aluminum pistons, and the distance between the top of the piston and the central axis of the piston pin is increased from 2.750 to 2.785 in., which gives approximately 1 cu. in. less clearance volume, making the compression ratio 5 to 1 instead of 4.94 to 1.

The clearance allowance corresponds to 0.005 in. per inch of bore at the head end and 0.0025 in. per inch of bore at the skirt.

A NEW Danish process by which certain by-products, valuable for electrical insulation, may be made out of fish offal, is soon to be put to practical test in Skagen, Denmark, according to the United States Commerce Reports. The most important of the new products is called "cornimit," and a factory known by that name is now being erected. It is claimed for "cornimit" that it excels galalith as an insulating material.

# Intensive Training in An Aircraft Plant

*Learning to assemble wing floats*

**Curtiss Company's School  
Has Capacity of 200 to 300  
Operatives Per Week**

**Women Develop Skill After  
Short Instruction  
Period**

By Frank L. Glynn\*

develop the skilled help needed, the company set aside a good-sized space on a mezzanine floor, approximately 5000 sq. ft., as a central training department. This space was supplemented by adding other suitable spaces in the various productive departments throughout the plant so that a total of more than 10,000 sq. ft. is now used for purposes of instructing unskilled new employees.

It has been found desirable to train operatives in several places in the plant rather than to have all of the training done in one larger central department, as there are some operations which do not lend themselves to the purpose of training when this is attempted outside the regular production department.

To-day the complete training system has a capacity of between 200 and 300 persons per week. The number

**N**OT long ago the man had to steal his trade. Yesterday the trade stole the man. To-day industry is filling its needs for skilled operatives by training the unskilled. And now the shortage of skilled labor has been followed by a shortage of men which will constantly increase as the army and navy grow.

The Curtiss Aeroplane & Motor Corporation of Buffalo, N. Y., faced the labor shortage problem in a very intensive way during the past winter, and in April last opened a training department which has since developed to such a degree that it can produce upwards of 10,000 operatives a year, trained for production.

Owing to the shortage of men, an experiment was made with women, resulting in the greatest of satisfaction, as shown by the fact that the foremen's requests for help during a recent month showed an increase of nearly 100 per cent for women over the previous month. Many of them now say that properly trained women are much better than the men they were able to get.

As soon as it became evident that something must be done to

*Beginners in the "dope" room. Young girls and middle-aged women are among the applicants*

\*Director of Production Training, Curtiss Aeroplane & Motor Corporation

**AUTOMOTIVE INDUSTRIES**  
**THE AUTOMOBILE**

*Learning the intricacies of wing assembly under the watchful eye of the male instructor. Fully 98 per cent of the women who have entered the employ of the Curtiss company had no mechanical experience*

*Female instructors teach beginners the various operations of the sewing department. By intensive methods the learning period has been reduced to an average of about two weeks*

*Women are taught and employed for even some of the heavier operations in the shipping department. A number of girls are here being shown how to crate wings*

trained each week has been constantly increasing from a relatively small beginning. The actual average per week of new employees trained during a period of four months is 87.

As to the cost of training, it can be said, as can of course be said of all such training systems, that the actual cost must be considered to be the difference between the cost of production in the training department and in the regular production department, and in calculating this cost the additional overhead in the form of instructors' salaries, spoilage, etc., must be taken into account.

In the Curtiss plant it has been found that the average gross cost of training has been approximately \$35 per individual, and the net cost, figured as above indicated, averages between \$7 and \$9 per employee.

Instructors have been developed from those already in the company's employ as mechanics or operatives and by taking shop instructors from schools and giving them actual production experience in the department of the factory for which they are to train help.

At first there was considerable objection to introducing women operators, as aircraft work requires a high degree of skill, and the consensus of opinion was that "women don't know anything." Without question, fully 98 per cent of the women who have entered the Curtiss employ never had any previous mechanical experience, yet the number of unsuccessful ones out of the thousand promoted from the training department during the past three months was negligible. The elimination came during the training period, which averaged about two weeks' time. During these two weeks, however, many were saved who otherwise would have been failures, because the training work not only taught them the various operations, but also fitted them into the special work for which

they were adapted, thus reducing the turnover materially.

The actual work may be carried on anywhere, but the organization and operation of the training department must be segregated and its departmental relations must be carefully planned or it will cause as much trouble as the "youngest in the family" usually does.

This, however, is a matter of detail in the original layout for the introduction of the training work and varies greatly with the individual plant or type of factory organization. After the work is successfully begun, it is comparatively a very simple matter for any factory to maintain it through the usual factory force.

If the original plan of organization be right, the training department will turn over with such rapidity that the cost should be reduced at least 50 per cent over what it otherwise might be; just the same as in the production of materials. This means one-half the floor space, one-half the equipment, one-half the instructive force and one-half the wage cost for the learning period. Then, too, the matter of properly intensifying the "learning period" to reduce it to the shortest possible minimum is exceedingly important in this respect and depends entirely on the original layout of the plan for operating.

The Curtiss work was the pioneer effort in the United States for the training of a large number of operatives daily in a short period of time. Green people were taken in and trained in an average of two weeks' time where the old shop practice would have taken at least six weeks with but little assurance of success.

Thus the training department in the Curtiss plant has been a saving to the company and the Government instead of a disbursement, besides which it assures the placing of employees in the proper place for highest pro-

duction and personal satisfaction.

Actual production orders are taken for the training work and no practice work or imitation miniature articles are built, and all work is done on a time-study basis. The people are trained on the real article and the real machine, so that when turned over to the production department they can give real service.

The result has been that the labor needs of the factory can readily be recruited, production carried on to better advantage during the learning period, the turn-over decreased, and the foremen are much more highly pleased at receiving the trained worker, made to order, than having to deal daily with green help.

We do not feel that we have solved the problem for all factories, nor do we feel that this is a panacea for all the labor ills, but for the Curtiss company the training department has rendered a large service in production training from fitting a girl to use a hammer and saw, milling machine, weld or braze, all along the line even to training for inspection.

Each factory is a problem in itself, depending upon its particular type, method and volume of production, and the numbers employed, so that this article is presented

*Propeller finishing is another of the operations which the Curtiss company now has done by women. These beginners will soon be put into the regular production department*

more as a suggestion of possibilities rather than information for any one to use as a patent medicine to cure all the ills that flesh is heir to.

### New Foot Warmer for Aviators

**A**N electric foot warmer for the use of aviators, drivers, etc. has been invented by W. W. Lillard, 200 Telle Avenue, Jersey City, N. J. Mr. Lillard, an engineer, is at present on active service, and the invention is being promoted by Ernest J. King, of the same address.

The equipment comprises an insole of the same general appearance as the common slip insole, except that it has two small plugs at the heel, which project about one-eighth of an inch into the bottom. These plugs are the terminals for the heating unit which is imbedded in the insole. The insole is placed in the shoe the plugs fit snugly into small sockets which are sunk in the heel about one-eighth of an inch.

There are two different ways for conducting current to the contact sockets in the heel. One consists in having two thin metal strips extend along the outside of the shoe to the heel for the distance of about an inch, these strips are adapted to make contact with contact plates in the foot. The other method consists in bringing two very thin wires down the back of the shoe inside the back stay to the contact sockets, connection being made at the top of the shoe by two small snap-fasteners which are barely visible. One wire is fastened to the inside seam of each trouser leg, and the other to the waist, where connection may be made with an electrical source. In making connection in this way absolutely no wire to get in a person's way.

It is claimed that a person equipped with this device can keep his feet as warm as he wants to, and that when his feet are warm his whole body is warm. The heating element is intended to be operated from a 6-volt battery, and the heating element has a resistance of about 6 ohms, the current consumption is only one ampere.

### Exhibition of New British Products

**T**HE British Science Guild has organized a comprehensive exhibition of products and appliances of scientific and industrial interest which, prior to the war, were produced chiefly from enemy countries, but are now produced in the United Kingdom. The exhibition, which is being held at King's College during August and the first week of September, contains, in the first place, products chiefly imported from Germany before the war, but now made in England. It also illustrates the remarkable developments that have taken place generally in British scientific industries in the past few years.

*Screw machines are operated almost exclusively by women in the Curtiss plant. They were all trained in the company's school*

# The Peoria Kerosene Tractor

Assembled of Parts Produced in Specialized Plants—Engine, Clutch and  
Transmission Bolted Together—Drawbar Hitch Can  
Be Laterally Adjusted from Driver's Seat

**A** TRACTOR of 12-25 hp. rating made largely of parts of specialized manufacture is produced by the Peoria Tractor Corp., Peoria, Ill. The current product is referred to as Model J and is equipped with a Climax kerosene engine of 5 in. bore by 6½ in. stroke (510.4 cu. in.). The clutch is a Borg & Beck and the transmission a Nuttall, so the machine is composed mainly of well-known parts.

The frame is built up of 6-in. heavy channels which are tied together by three ½ x 6 in. steel plates, bob riveted. To the forward end of the frame is riveted a front axle pedestal, made of ½ x 6 in. steel plate. This pedestal extends from side to side of frame, but is stiffened by props at the center. An unusual design of front axle is used. It is certainly somewhat crude looking and emphasizes the need for specialized tractor axle manufacture which has been advocated in these pages. The main element of the axle appears to be a length of Tee iron, to the top flange of which are riveted two suitably bent pieces of strip iron to form the steering yokes. These steering yokes extend about half way to the center of the axle and are made so long to permit of the steering arm on one of the knuckles, to which the drag link is connected, to swing through it. At the center a swivel bracket is bolted to the axle, to which connects a swivel post through which the weight of the frame is carried on the axle. A coiled spring supports the frame on the vertical post. The details of construction of this spring mounting unfortunately cannot be clearly made out from the illustration. To take up any lateral thrusts on the axle two radius rods are run from it to a frame cross member back of the engine. The two steering knuckles are identical in design and therefore are interchangeable. The front wheel spindles are made of cold-rolled stock and are secured into the knuckles by means of nuts. The arms for the tie rod are formed integral with the knuckles but the arm for the drag link is bolted on.

It is not necessary to say much about the engine, as this has been fully described in a previous issue of *AUTOMOTIVE INDUSTRIES*. It may be recalled that it is a four-cylinder machine of 5 in. bore by 6½ in. stroke (510.4 cu. in. displacement) and is designed to operate at 650-800 r.p.m. The power rating is 34 hp. An enclosed governor is fitted and the cylinder heads are detachable. The engine is specially designed for operating on kerosene, there being a deep water space above the combustion chamber and the spark plug bosses in the cylinder head being completely surrounded by water.

A 1½-in. float feed type of carburetor is used, specially adapted for working on kerosene, and ignition is by an Eisemann magneto with impulse starter. Magneto, governor and water pump are located in line at the side of the engine and driven through the same gear train. The engine is supported by four arms cast on the crankcase and bell housing, directly on the main frame. The radiator is a Eureka with copper tanks and the radiator fan an Oakes mounted on ball bearings and driven by a 2-in. flat belt. The air taken in by the carburetor is drawn through a Bennett air cleaner.

Fuel is carried in two cylindrical tanks resting on top of the frame back of the engine space. The kerosene tank, which is closest to the engine, has a capacity of 22 gal. and the gasoline tank 5 gal.

## Unit Power Plant Construction

As already pointed out, a Borg & Beck plate clutch is used, this being a special tractor design and having its front end supported on a ball bearing. Directly back of the clutch is the Nuttall transmission, which affords two forward speeds and one reverse. This transmission, which is enclosed in a cast-iron case, comprises not only the change gears but also the jackshaft and differential, as well as a belt power take-off shaft. All gears are made of medium carbon steel, and

*Plan view of Peoria tractor with hood removed*

*Three-quarter front view and rear view of tractor*

after the teeth are cut the gears are hardened and ground. The shafts are of forged steel, hardened and ground. They are mounted in Hyatt roller bearings. The case is partly filled with oil and is provided with a very large cover plate admitting of easy access to the gears, bearings, etc. Shifting of gears is effected on the selective principle and a lock is provided which makes it impossible to engage two sets of gears at the same time. The two forward speeds are  $2\frac{1}{2}$  and 4 m.p.h. respectively.

A power take-off shaft extends from the gear case over the top of the side frame and carries a brake pulley and a belt pulley. The belt pulley is 14 in. in diameter, with a 7-in. face, and at 800 r.p.m. of the engine gives a belt speed of 2400 ft. per min., the gearing being such as to give 650 r.p.m. of the pulley shaft at 800 r.p.m. of the engine crankshaft. It will be seen that the belt pulley extends beyond the rear wheel, which has the advantage that the belt can be run either to the front or rear. The long overhang of the belt shaft tube detracts somewhat from this advantage, however. The brake drum is of very small diameter and the way the brake contracting gear is designed it must impose very considerable pressure on the outboard bearing of the pulley shaft when the brake is applied. The brake is controlled by the same pedal as the clutch, the first motion of the pedal releasing the clutch and continued motion applying the brake, which latter is faced with Non-Burn friction lining.

Final drive to the rear wheels is by internal gears. The pinions for the final drive are secured to the ends of the jackshaft forming part of the Nuttall transmission. There are pads formed on the jackshaft tubes by which the transmission is supported on top of the main frames.

#### **Rear Axle of Cold-Rolled Stock**

The rear axle consists of a cold-rolled steel bar  $2\frac{15}{16}$  in. in diameter and 64 in. long. It is fastened to the frame by means of two adjustable axle brackets. By means of these brackets the driving pinions can be brought into accurate mesh with the internal gear bull rings on the rear wheels. A further advantage claimed for this axle construction is that when the axle spindles in the wheel hubs have worn on one side, the axle brackets can be loosened up on the axle and the latter turned half way around. Whether this would materially improve the running conditions is to be doubted, however. It will be seen that the internal gears are very large in diameter, not much less than the diameter of the wheels. This permits of the use of relatively large pinions and cuts down the tooth pressure—a desirable feature where the gears are not enclosed.

Driving wheels are 56 in. in diameter and have a rim 12 in. wide. They are of the all-steel type, the spokes being riveted into both hub and rim. A noteworthy feature is a removable cast-iron bearing sleeve 14 in. long. Most of the wear of the axle bearing undoubtedly comes on this sleeve, which can be renewed when the play becomes excessive.

The drawbar is hinged to the frame at its forward end and its rear end has a range of lateral motion of 20 in. This motion is controlled by a lever conveniently located at the side of the driver's seat, enabling the driver to shift the hitch while the tractor is in motion. This feature is of value particularly in side-hill plowing, when there is a tendency for the plows to change the width of the furrow, which tendency can be corrected by means of the hitch lever.

A drawbar plate  $5\frac{1}{2}$  in. wide is located directly under the rear axle and is riveted to the frame. The rear axle is secured to this plate by  $\frac{3}{4}$ -in. U bolts. The drawbar is 18 in. high from the ground.

The front wheels are 30 in. in diameter and are provided with guide rings. It will be observed that the rear wheels are shown without lugs, and evidently no lugs are included in the regular equipment, though the wheel rims are punched for lugs.

Steering is effected by means of an enclosed worm and gear mechanism of the Peoria company's own design. The steering gear is operated by means of a hand wheel with handle and the steering post is supported at its upper end by a bracket bolted to an angle iron structure secured to the frame. On the rear end of the frame is a wooden floor on which are mounted the driver's seat and the gear control bracket. The combined clutch and brake pedal is directly in front of the driver's seat, which latter is of the ordinary plow type.

The Peoria tractor has a wheel base of 96 in. and weighs approximately 4900 lb. As its drawbar rating is 12 hp. it should develop a drawbar pull of 1800 lb. The belt power rating is 25 hp.

# Some Outstanding Problems in Aeronautics\*

## Material for the Different Elements of a Plane—Problem of Size Limits—Variable Wing Area and Camber—Aircraft Engines

By Dr. W. F. Durand

**P**ERHAPS nowhere is there to be found a better illustration of the interdependence of technical and scientific research and study than in the manifold advances in various technical and scientific lines which conjointly have made the aeroplane in its present form a structural possibility.

Broadly, the modern aeroplane comprises a body of some sort or form fitted with wings to provide the supporting surfaces, with a prime mover or source of power and with a propeller of some type to transform the power provided by the prime mover into propulsive work, and by the reaction of the relative air stream on the under side of the wings, to secure the sustaining or lifting force necessary to carry the weight. This construction calls for a wide range of constructive materials. Thus the body and wings, comprising the aeroplane proper, require the following fairly distinct classes of structural elements:

(1) Those intended primarily to give form, strength and coherence to the structure. They represent in effect the skeleton or foundation on which the entire function of the aeroplane as such must depend.

(2) Various secondary elements intended to so tie or connect the principal members together as to secure homogeneity of structure as a whole, and mutually responsive action on the part of the different elements comprised under No. 1. The elements here considered are those which, from a purely structural viewpoint, may be classed as struts and ties or tension members, with suitable connections and joint fastenings.

(3) Surface covering for the body and wings. This gives outer form and continuity of surface and provides furthermore the actual surfaces on which the air lifting and supporting forces may act.

Broadly speaking, the fundamental problem in all aeroplane construction is adequate strength or function on minimum weight. In no other form of engineering construction is the necessity for weight saving so rigorous. In a very real sense every ounce of material entering into the structure must be able to show a competent passport. The structural problem of the aeroplane is therefore one of strength in relation to weight. For the main elements comprising the skeleton of the structure, wood has, thus far, held the main place, with metal construction steadily attracting more and more interest and assuming a place of growing importance, at least in the study of new designs.

It is not necessary to our present purpose that we should consider in detail present practice in aeroplane construction. The trend of development since the earliest days of the art has tended to show that wood construction under suitable design and safeguard was able to provide the easiest and on the whole the most satisfactory solution of the many problems and requirements which aeroplane construction presents, and so we have been content, for the most part, with this type of construction.

We may, however, be well assured that no matter how good may be any solution which we may reach of the many problems presented to us in the industrial arts, there are, as a matter of fact, series of better ones only awaiting our patient

study. This is indeed a fundamental truth of which we should never lose sight. We may be, for the moment, satisfied with our solution of a problem in technical industry; we may be able to see nothing better, and yet we may be well assured that, as a simple matter of fact, there is something better. This is a perfectly safe assertion, if only as based on the law of probability of our having, at any given time, reached the final optimum possible combination capable of furnishing a solution of the problem.

Thus, as applied to the problem of constructing the framework of the fuselage of an aeroplane or of combining together wing spars and ribs in such manner as to form a wing skeleton, we may be sure, however satisfactory our present practice may seem and however good it may really be, that in reality it is not the best and that long series of better solutions only await our intelligent and patient study.

In this and in all such problems there are always two fairly distinct though interrelated parts:

(a) What materials are best suited to the purpose in view.

(b) What disposition shall be made of the materials adopted.

Thus, in the case of the fuselage, granting wood material to be adopted, there remains the question as to the very best distribution of such material as between the main longitudinal elements, or longerons, and the intermediate elements; also as to the extent to which reliance may be placed on the outer covering, especially if of ply-wood. What aeroplane designer can feel sure that, even with given materials, he has reached the optimum distribution of function as between the main and secondary elements of the fuselage and of a ply-wood outer covering?

Much less, what aeroplane designer can feel any confidence in having now reached an optimum combination, once we admit the possibility of metal construction, or of some combination of metal and wood, with all the possibilities of the new light metal alloys and of the new alloy steels with their astonishing physical characteristics.

So far as conditioned by the application of the ordinary loading test, static in character, and aside from the possible results of dynamic attack, shock, long continued vibration, etc., we may perhaps frankly admit that the present state of metallurgy is able to supply us with material, either in the way of light aluminum alloys or special steel alloys, which if properly used will enable us to meet all such static tests in an aeroplane construction, and on even terms or better as regards weight compared with wood.

If such is the case, it certainly stands before us as a problem for the near future to pass in review most thoroughly the entire range of constructive materials, metallic as well as wood, and to determine, in the light of the experience which we are so rapidly accumulating during these days of storm and stress in military aeronautics, the combinations of materials which may assure the most efficient service on the minimum of weight.

In connection with this search for new and better materials must go hand in hand search for better modes of combination in the structure—in other words, better structural design. It goes without saying that the best general type of design, in the way of the distribution of materials, forms and proportions of members, etc., will vary with the class of

\*Sixth Wilbur Wright lecture read before the Aeronautical Society of Great Britain at London, June 25.

material employed. There must be some optimum design with wood. There will likewise be another and undoubtedly a different optimum design in the case of steel, and again different in the case of aluminum or other alloys. Thus the search for the best final combination is a search for an *optimum optimorum*; for the best possible material and for the best possible design using such material.

What order of saving may be looked for in the near future from any such search it is, of course, idle to predict. Could we, however, approach somewhat closely to the best use of the best combination of materials even now available in the field of engineering construction and without waiting for new and superior materials which the metallurgical art will doubtless be able to furnish, it seems not unreasonable to anticipate the possibility of a marked saving in weight without loss in strength or security.

This then stands out as one of the great problems of aeronautic engineering, that of the best materials and their best use. Much has already been done, but much yet remains, and rich rewards most assuredly await patient and well directed work in this field.

### The Problem of Size

One of the most interesting of the problems presented to the aeronautic engineer is that of the limiting size and carrying capacity of aeroplanes. Is there such a limit? If so, what is it? Why is it? And how may it be removed or extended?

In dealing with this problem we come, of necessity, into contact with the laws of similitude of geometrically similar structures. It is well known that under simple modes of loading, geometrically similar structures of wing and fuselage will have similar factors of safety under equal unit loads. But for such structures, if strictly similar geometrically, the weights themselves will increase as the cubes of the similar dimensions, while the areas of wing or supporting surface will only increase as the square, and hence the ratio of weight to area will continuously increase as the linear dimension.

Under these circumstances, it is readily shown that, in accordance with the relation of the factors involved, there will be for any given speed, some size for which the lifting capacity over and above the structure itself will be a maximum and above which the lifting capacity over and above the structure will become less and less with increase in size, gradually reaching zero for some value of the size of the structure. This would mean that at such point the supporting force developed at the speed in question would be just enough to lift the structure itself from the ground, but with no reserve for additional load.

This is, of course, a definite law derived from well known principles of geometry and calculus, and if it were the whole story, it would indeed tend to raise an insuperable bar before continued expansion in size. If such were the case it would mean in effect that increase in lifting capacity could only be reached by the following measures:

(1) Reducing to a minimum the relation of weight of structure to area. That is, general improvement in the program of design and reduction of weight of structure in relation to supporting surface.

(2) Reducing to a minimum the resistance of the plane at the given speed and likewise the relation of weight to horsepower.

(3) Raising to a maximum the relation of lifting force to area, consistent, however, with the decrease of the total propulsive resistance of the plane.

Were we indeed subject, without recourse, to the operation of this law of mechanics and geometry we should be in a sorry state regarding the future development of the aeroplane as regards size and carrying capacity. We should be limited strictly within the bounds of the developments made possible by improvements and advances along the lines as indicated above. But fortunately for the future of aerial navigation, we are not so limited and there seems no reason why, at the present time at least, we should need to anticipate any especial limit as necessarily imposed on aeroplane construction, as regards either size or carrying capacity.

We are able to escape from the consequences of this law by reason of two facts.

(1) It is not necessary that a large element of an aero-

plane, a wing in particular, should be geometrically similar in structural characteristics to a smaller one. For a certain size the structural elements will partake of certain characteristics. As the over-all size increases, these elements may take on new characteristics. Those which had been solid may now become hollow or of lattice or built-up form. The law of geometrical similitude will not hold, and the weight will not necessarily increase in ratio with the cube of the over-all linear dimensions.

(2) It is by no means necessary that a large aeroplane shall be, in its general form, a geometrical copy of a small one. While both will have similar elements, such elements need not be the same in number or arrangement. In fact, one of the most obvious of means for increasing lifting power is to increase the number of the wings or lifting elements. There is no reason, at least structurally, why wings and connecting elements should not be increased in number beyond anything now in use or even considered—increased to a point which would give a size and lifting power great enough to meet any demands which we can now formulate or which the future seems likely to present.

Structurally, therefore, the problem of increased size presents three problems, as follows:

(1) The structural problem of so developing the character of the elements of aeroplane construction such as wing spars, longerons, struts, ribs, etc., that with increase in over-all dimension the weight shall not increase sensibly faster than as the square of such dimension.

(2) The structural problem of combining the larger elements of aeroplane construction such as wings, fuselages, or engine nacelles with their connecting structures, in such manner as to secure, for a given wing area, the minimum weight of secondary structure.

(3) The aerodynamic problem of combining multiple wing elements in such manner as to reduce to a minimum the interference of one with another. This is a problem which opens fascinating possibilities to the student of experimental aerodynamics—a problem on which already some beginnings have been made, but one far from a final or as yet wholly satisfactory solution, and one on which the future development of greatly increased size and carrying capacity seems destined to largely depend.

In short, then, so far as increase in size is concerned, there seems no reason to apprehend any particular limit, or any serious difficulty on the part of the scientist and the engineer in meeting the demands of the future in these respects. The difficulties seem no greater than those which have been overcome in the case of ocean shipping as shown by the continuous development from the early beginnings of the application of engine power to ocean navigation during the first half of the last century down to the mammoth floating structures of the present time; and if we may take any indication from the accelerated rate of progress which has characterized the entire history of aerial navigation, we may feel confident that we shall not have to wait a half or three-quarters of a century for a parallel development in the latter field.

### Variable Wing Area or Variable Wing Camber

To mention only one of the many remaining problems which are connected with the design and construction of the aeroplane itself, a word may be said with regard to the problem of variable wing area. Broadly speaking, the ideal aeroplane should be able to change its wing area in accordance with the conditions and circumstances of flight. For ease in getting off the ground at a moderate speed, for ease in landing likewise at a moderate or low speed, there is need of a relatively large area of wing or supporting surface. For the attainment of high speed, reduced wing areas are needed, and are furthermore sufficient for the support of the weight at such high speeds. The supporting force gained by a given form of aeroplane wing depends on the area, the speed and the angle of attack, and there will be some combination best for each set of conditions. To meet these conditions, varying from time to time throughout the course of a flight, a correlative variation in wing area is needed.

To some extent the same ends may be met by changing the camber or curvature and form of the fore and aft section of the wing.

Thus, when the camber or fore and aft curvature is in-

creased, the form will be more suitable for landing at a reduced speed, while with curve flattened and camber reduced, the form will more readily favor the attainment of relatively high speed.

The problem of an adjustable wing, either as to extent of area or camber or both, is a favorite one with students of aeronautics, and we may hope for some measure of useful and practical solution. Thus far, of the many devices and forms proposed, none has so far fully justified itself as an altogether satisfactory and practical solution of the problem.

#### Motive Power

Passing now to the motive power and its application to the propulsion of the aeroplane, a most interesting and important series of problems challenges our attention. Only the more important can be noted here.

One of the most important of these is that of fuel. What is to be the future fuel for the aeroplane, or for aerial navigation in its wider aspects? How long will our stores of crude petroleum oil from which we now obtain our petrol or essence or gasoline, as it is variously termed, continue to furnish this all-important element in the present program of power development? Doubtless there are large stores of petroleum oils yet undiscovered, but we may safely assume that we are using up a supply in the nature of a bank deposit. We are using our principal, and not living on the interest. So far as we know, nature is not now engaged in making for us petroleum oils, certainly not in any proportion to our rate of expenditure. To such a general program of consumption there is, of course, but one end, ultimate exhaustion.

This is, of course, only one phase of the overshadowing menace which the modern social and industrial world must face some time when our present supply of carbon and hydrocarbon fuels begins to become exhausted, unless indeed we develop or discover in the meantime some other source of energy which will adequately take their place. This is perhaps a question which need not seriously concern the present generation, but when we take a long look ahead—a look, for example, as long as that covered by the development of Europe from the days of the Cæsars or even from the time of, say, Galileo—we may realize with startling emphasis the need of foresight with regard to a source of energy adequate to the world's demands. Various ages have been designated as of stone, bronze, etc. The present might well be designated as that of natural energy. Our entire civilization, in a material sense, rests upon the utilization of sources of natural energy which are not inexhaustible and which are, in fact, becoming exhausted, in some cases, with menacing rapidity. In the meantime we must, and presumably we shall, make some shift to tap efficiently other sources now known, or we may haply discover sources which to-day lie beyond our present vision.

#### Fuel Problems

A long look ahead for aerial navigation therefore shows that if the present line of development is to continue, there will be a serious problem to be met some time, and that perhaps before many decades—the problem of a fuel suited to the needs of aeronautic prime movers, at a time when present petroleum sources will no longer yield the supply which we now accept and use with so little thought for the requirements of to-morrow.

But with regard to the question of fuels, we need not go so far afield as to look into the coming decades for interesting and important problems. Perhaps the one most pressing for present solution is the question of what is the best fuel for the modern aviation engine, having in view the three requirements—power, economy, with reliability and durability. Out of the exigencies of the present war have come many serious and extended researches relating to the problems of military aviation, and of these none is perhaps of greater significance regarding the future of commercial aviation than the studies which have been made regarding aviation fuels.

While matters relating to the problems of military aeronautics must be spoken of with much reserve, it will perhaps be permissible to say before this audience that from these studies three principal results seem to have been rather definitely established. These are:

(a) As between the various grades of aviation motor fuels which have been used during recent years, and comprising a rather wide range of composition and of physical and technical characteristics, there is but little to choose from the standpoint of power or economy alone. This assumes, of course, that the fuel is a genuine motor fuel and the results regarding power or economy relate to an assumed period of effective operation under such fuel. It must not, however, be assumed that there are no differences in power or economy traceable to the fuel employed, for such is far from being the case. It is, however, within the limits of reasonable statement to say that such differences are relatively small and under most circumstances would not, of themselves, constitute a determining or controlling factor.

(b) As between such motor fuels marked differences do seem to be indicated as regards their influence on the life and reliability of the motor, especially on long time tests, or in actual service on long time flights.

(c) For the various fuels, in order to realize the best results either as regards power, economy, or life and reliability, special and individual carburetor adjustments are necessary, and such as can only be determined by trial under actual working conditions.

#### Present Fuel Satisfactory

It may perhaps be further said that the problem of an excellent and reliable motor fuel for aviation purposes seems to have been satisfactorily solved. Its specifications and range of characteristics, physical and chemical, are pretty well established, and so long as our source of motor fuel supply is to be found in petroleum derivatives, we seem to have reached a reasonably satisfactory determination of the best combinations of such derivatives for the various requirements of aviation service. These characteristics, which must be considered as a part of the great body of military information and which cannot for the moment be put down in plain print, we may hope will, in due time, become available in the arts of peace and for the development of commercial aviation in its various fields of promise.

(To be continued.)

#### New Spring Lubricator

THE McCormick Laboratories Co., Dayton, Ohio, has investigated the problem of leaf spring lubrication and has developed an interleaf lubricator which, it claims, overcomes all the difficulties experienced with leaf springs when unlubricated or lubricated in the primitive way by means of a table knife or paddle. The interleaf lubrication evolved consists of a fabric tube which is slipped over every second leaf. This tube is impregnated with lubricant. With this lubricator, it is claimed, the spring leaf surfaces are permanently and uniformly lubricated, the compressible character of the tube compensates for inequalities in the leaves and makes for uniform distribution of pressure. The lubricator prevents water and grit from entering and consequently prevents rusty, frozen leaves.

The McCormick Laboratories Co. does only research and development work and is not engaged in manufacturing.

# McElroy Kerosene Engine

Has Sliding Valve Positively Operated by Double Cam Mechanism—Fuel Charge Heated in Combined Inlet and Exhaust Manifold and Standard Carbureter Used

**A**N engine embodying a novel form of sliding valve and burning kerosene as well as gasoline is manufactured by the McElroy Engine Co., 909 Clifton Avenue, Newark, N. J. It is being regularly manufactured in small lots for stationary work, and several four-cylinder models for motor vehicle purposes have also been built.

The slide valve is of crescent shape and operates in a pocket turned eccentric with the cylinder at the upper end thereof. This sliding valve is moved up and down positively by a double cam mechanism on a half-speed shaft. One cam raises the valve and the other returns it. Each cam has a roller follower, and the two rollers are, of course, carried by the same push rod, which has an extension saddling the camshaft.

*Sectional view through cylinder showing sliding valve and valve-operating mechanism*

In order to prevent the slide valve from leaving its surface under the influence of suction in the cylinder it is held to same by a rod extending through the combustion chamber and having a spherical seat in the end of a screw screwed into the cylinder wall on the opposite side.

Inlet and exhaust ports are formed in the cylinder wall at the valve pocket, the inlet ports below and the exhaust ports directly above. The two manifolds are in one casting and as a result the incoming charge is heated by the hot wall of the exhaust passage. This is the only heat supply to the charge and is said to be sufficiently effective to permit kerosene to be used as fuel. An ordinary gasoline carbureter is used of any well known make. As a matter of fact, two carbureters are fitted, one for gasoline and the other for kerosene, and the two valves are interconnected, so that as one is opened the other is closed proportionally.

Other features of the engine are conventional. The cylin-

*Top view of cylinders with cylinder heads removed and valves in place*

der heads are detachable, which facilitates removal of the valves and cleaning of the combustion chambers when necessary. Camshaft and magneto shaft drive is by a silent chain. The crank case is divided in a horizontal plane through the crank axis. Lubrication is by the circulating splash system.

## Book Review

**A**UTOMOTIVE Magneto Ignition, by M. E. Toepel, published by Spon & Chamberlain, 120 Liberty Street, New York. 103 4½ x 7½ in. pages, bound in limp leather. Price, \$2.

This little book is intended as a guide to practical men having to look after magnetos on various types of automotive vehicles. It is in the form of a catechism, and contains some 200 questions and answers thereto. The author is at present engaged as instructor in the U. S. Government school for the study of magneto ignition, and apparently has had in mind the needs of his pupils. Reference to specific types of apparatus and minute details have been avoided, and the book is not descriptive in any sense.

*The four-cylinder McElroy engine, showing inlet, and exhaust ports in cylinder walls*

## Tractor Gear Ratio Chart

*To find the gear reduction required to give a certain tractor speed with a given engine speed and drive wheel diameter, proceed as illustrated by the example shown in dash-dotted lines. Start with the engine speed on the bottom scale, pass vertically up to the inclined line denoting the wheel diameter, then horizontally to the right or left to the inclined line denoting the tractor speed, and then vertically up to the top scale, where the required gear ratio may be read off*

## Entz Magnetic Transmission on Fifth Avenue Bus

SOME eight months ago the Fifth Avenue Coach Company, New York, installed an Entz magnetic transmission on one of its standard Model A buses, and placed the machine in regular service. Each of the buses operated by the company carries about 300 passengers per day, and as an average of four stops are made per passenger, it is readily realized that the strains on the clutch, brakes and transmission are very severe. With the Entz magnetic transmission no friction clutch is required, nor are there any clashing gears, and if this transmission could be properly developed for this particular service, a material saving might be effected.

The installation of the transmission was made by the Entz Motor Patents Corporation of New York, and was completed on November 28, 1917. The bus with Entz transmission complete weighed 10,180 lbs., of which 3,810 lbs. was on the front axle and 6,370 lbs. on the rear axle. This weight is made up of the chassis weight of 6,466 lbs., of which 3,150 lbs. is on the front axle and 3,316 lbs. on the rear axle, and of the body weight of 3,714 lbs., of which 660 lbs. is on the front axle and 3,054 lbs. on the rear axle. The bus with the Owen magnetic transmission is 890 lbs. heavier than the regular type A bus of the company.

During one month's service, ending January 6, 1918, the Owen magnetic equipped bus showed a fuel consumption of 1 gal. per 4.3 miles, as compared with 1 gal. per 5.4 miles for the standard type bus. This showing, however, was materially improved later on.

From December 6, 1917, to January 26, 1918, the bus

ran 4,605 miles. Between December 6, 1917, and January 19, 1918, it showed an oil consumption of one gallon per 244 miles. During the period from December 30, 1917, to January 26, 1918, the fuel consumption was at the rate of one gallon to 5.7 miles.

During the month of March the bus ran 2,495 miles. Between March 3 and March 31, 1918, the oil consumption was at the rate of 1 gal. per 279 miles, which was 64 per cent better than the showing of the standard A type bus, and the gas consumption was at the rate of 1 gal. per 5.6 miles, which was 12½ per cent worse than the standard type A bus.

During April and May the bus ran 4,887 miles and consumed gasoline at exactly the same rate as the standard type A bus and 33 per cent less oil than the standard type A. Between December 6, 1917, and May 31, 1918, the bus ran altogether 14,968 miles.

The troubles experienced during the period of observation were chiefly of a minor character, except that once the clutch and motor armature burned out, which was due to defective insulation. The driving shaft keys sheared off twice, and necessitated the installation of a new shaft and flange.

The engineers of the Fifth Avenue Bus Company consider the experiment with Owen magnetic very successful, but since the company has already committed itself to the straight gasoline bus, to the extent of 300 vehicles, no more magnetic equipped machines will be placed in regular service at the present time. For later orders the system will receive favorable consideration.

## Vacuum Muffler Based on New Principle

A MUFFLER based on an interesting principle is manufactured by the Vacuum Muffler Corp., New York City. It consists of two castings of flat cylindrical shape open on one side. On the inside of each are a large number of radial partitions, and the two castings are so fitted together that the partitions on one enter between those on the other. The exhaust gases enter the muffler through a central opening in one of the castings, and the stream is broken up by a cone cast on the other. It is thus divided into a large number of small streams, which pass around the circumference of the muffler and then unite in the common outlet. As the paths of the different small streams are of unequal length, the exhaust gases, instead of being discharged all at the same time, are discharged gradually, thus avoiding the loud noise which is produced if an engine exhausts through a comparatively free outlet.

What undoubtedly adds to the efficiency of the muffler is

the fact that the gases are given an excellent chance to cool rapidly.

It is quite understandable that this muffler offers but little back pressure to the exhaust, as the latter does not have to follow a zig-zag path nor encounter obstructions in the shape of plates with fine perforations. It is claimed for this muffler that it remains entirely free from carbon. This is probably due to the fact that the exhaust gases pass through every part of it at considerable speed and thus give the carbon no chance to settle.

According to a test made by Joseph Tracy, an engine fitted with one of these Vacuum mufflers gave 4 per cent more power than when exhausting directly into the atmosphere. The test was made on a four-cylinder 30-hp. motor, and when operating without a muffler the exhaust passed to the atmosphere through a 15-ft. length of 2½-in. pipe. The fuel efficiency was improved in the same proportion.

# Preparing Men for War Tasks

General Motors Truck Co., Pontiac, Furnishes School to Train Men for the Sanitary Corps—Men Are Trained So They Can Repair Trucks Under Any Conditions

THEY call it "France"—the plant of the General Motors Truck Co., Pontiac, where men come from various cantonments for a thorough training in automobile mechanics for work in the Sanitary Corps of the United States Army. They work with tools that come with the truck, the same as they would in some isolated post in France. Under expert instructors they receive a 6 weeks' course, from which they are graduated to go overseas for duty on the battlefields or to cantonments to prepare other men.

The purpose of the course is to make the men so familiar with the parts of a truck that they will be able to recognize any part immediately and be able to properly adjust it in the least amount of time. They are taught just what parts to remove to repair others; how to interchange parts, and to replace any part that may have become defective through accident or wear and tear.

## First Squad Came in December

The first squad came to the General Motors for training in December from the aviation section of the Signal Corps. Another company of men came from Allentown, Pa., March 1, and other cantonments also have sent men to the plant for training.

A systematic course is pursued. Before any actual work is done the newcomers are taken on a tour through the factory. They start with the foundry, where they are shown what pig iron looks like, whence they are taken into the factory, watching the machine develop step by

*A company of men that came to the General Motors for training for the Sanitary Corps. All the men are under military supervision*

step into the finished product. The class is accompanied by instructors, one to a squad composed of not more than ten men.

For the most part the class is composed of men who are theoretical or practical mechanics having been graduated from engineering courses in colleges or having had training that puts them above the ordinary automobile mechanics.

## Ambulance Mechanism Studied

Having gone over the ground once and somewhat acquainted themselves with the course, the men start over again, this time specializing on the ambulance, analyzing each unit in minute detail. The frame and the method of mounting the various units on it are taken up first. The engine, clutch, transmission, rear axle and radiator

*A company of men receiving instruction in the workings of a truck chassis*

*The men specialize on the ambulance. The training received at the plant enables them to maintain a truck*

are next considered in turn. The engine, the most complicated part, is under discussion the longest period of time. A week is usually spent on this; 4 days are spent on the rear axle; 3 days on the clutch, and shorter periods on the other units. All this work is done by personal demonstration; all the parts are taken down and assembled by the men themselves with no other tools than those included in the regular equipment of the truck.

Having completed the course outlined in the foregoing, the men have a comprehensive idea of how to repair a truck, but they are not yet finished. They must be taught how to make adjustments and how to maintain the truck in service. Once again the men return to work on the engine for the purpose of acquiring a knowledge of making adjustments. Next the men are taught how to adjust steering rods, adjust tappets, grind valves, time magnetos, adjust carbureters, and all other service operations that may be called for "over there."

When the service of carbureters and magnetos is under discussion an expert on each is called in to give a talk on his respective line.

In all operations the shortest methods for replacing parts, repairing and making adjustments are taught. Time counts on the battlefield, especially in the ambulance unit, and the importance of this is not lost sight of in the course.

All the men attending the classes are under military discipline—all of them work from 8 to 10 hours a day and have one hour drill in the morning from 7 to 8 o'clock. Although under military supervision during the day, the men are privileged to go where they choose in the evening.

From the first bit of assembly through to the last, the Sanitary Corps follows the work carefully, in the knowledge that not the slightest detail of assembly can be missed. At the close of their training the men take two examinations, one written, the other demonstrative. It is necessary that both be passed with a certain grade. While both are extremely difficult, it is the demonstrative examination that meets with the most disfavor among the students.

For this latter examination it is required of the men to assemble a truck. Next a truck that has been tampered with is given them, and they are asked to find the trouble. Every sort of trouble imaginable is met with, and thus far none has failed in this particular section of the examination.

Instructors take keen delight in thinking up methods of tampering with trucks for this particular test. Among the things they do is to put small wooden plugs in the gasoline tube so that but a small amount of fuel will run into the carbureter.

### HORSELESS AGE SUBSCRIBERS

Subscriptions for the Horseless Age transferred to the subscription list of AUTOMOTIVE INDUSTRIES in the merging of the two publications will be completed in full by the weekly issues of AUTOMOTIVE INDUSTRIES to the dates of expiration shown on the records of the Horseless Age Co.

Owned by United Publishers Corporation, Address 243 West 39th St., New York; H. M. Swetland, President; Charles G. Phillips, Vice-President; W. H. Taylor, Treasurer; A. C. Pearson, Secretary.

Entered as second-class matter Jan. 2, 1903, at the post-office at New York, New York, under the Act of March 3, 1879.

Member of the Audit Bureau of Circulations.

Automotive Industries-The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907.

## Do Not Force the Issue

"IF the automobile industry would keep quiet, we could get up to 100 per cent of our steel requirements." This remark, made by the purchasing agent of one of the largest automobile factories in Detroit, sums up in a nutshell the opinion of many buyers of the industry.

The War Industries Board is a body of business men concerned with the winning of the war. Since the winning of the war is the biggest and most important business before this country at the present time, the wishes of this board take precedence over everything else in the country.

Since the War Industries Board is composed of good business men, it is but natural that when they are pinned in a corner by requirements for a ruling on material that they need, their first consideration is going to be what they require themselves. When asked to make a definite ruling, they are not going to estimate on a minimum but on a maximum. The result of this is that when the automobile industry

insists on a ruling regarding the amount of steel that it is to secure, the War Industries Board will take first into consideration the maximum amount which the War Industries Board will require to carry on its own business.

Steel authorities and those versed in manufacturing know that the War Industries Board *can never use up to the maximum* estimate of the steel it requires. They know that from month to month, as time goes on, there will always be a surplus over the amount required for war purposes. This surplus is large enough to take care of the important industries of the country to an extent fully in keeping with the reduced requirements of commercial manufacture, due to war-time conditions.

Purchasing agents for automobile factories have this well in mind. Their sympathy is not with those in the industry who insist on obtaining a definite ruling, with the result that the industry is in a hard and fast condition, with a minimum amount of material, instead of being in an elastic condition, with a quantity of material obtainable which would readily take care of the very limited demand now existing.

It does not take a minute of clear thinking to readily see that, regardless of all rulings and regardless of all requirements of commercial enterprises, the War Industries Board is first going to be served with the amount of steel it requires to carry out its program of winning the war. Over and beyond this quantity of steel, the highest authorities are agreed that there is sufficient to take ample care of industries working under a reduced war-time program. Let us stop forcing the war board into a corner where it is compelled against its wishes to make rulings which will not be favorable to continued commercial manufacture.

## The Tractor Seat

THE average tractor is equipped with the regulation cast seat which has become standardized on sulky plows, binders and other agricultural machinery. Recently an attempt has been made to provide more comfortable seats for tractors, and this movement bids fair to gather force and lead to a complete change in the design of seats. It certainly seems reasonable that the tractor seat, which the farmer occupies almost without intermission from morning till night, should be at least as comfortable as his automobile seat, which he seldom occupies more than a couple of hours at a time.

Probably the habit of many farmers of leaving their machinery out in the open during long periods of non-use, exposed to the weather, had considerable to do with the adoption of the cast iron seat, for properly painted cast iron bears this treatment remarkably well. The provision of a comfortably upholstered seat with arm rests and back would appeal to some farmers as an improvement, while it might prejudice others as rendering the tractor less weather-proof. It might have the effect of inducing farmers to take better care of their tractors, to provide proper housing facilities and to put them up as soon as their work in the field is done.

# Aircraft Report Unfair to Industry

Evidence in Hearings Shows Army, Navy and Government Departments Also at Fault

By DAVID BEECROFT

**A** PART from the justice or injustice of the aircraft report by the sub-committee of the Committee on Military Affairs, United States Senate, only one dominating conclusion can be reached, namely, that there is grave necessity for a supreme head of all aircraft activities; and while the appointment of John D. Ryan as an Assistant Secretary of War is a step in the right direction, it is only one step, and the satisfactory working out of the aircraft task cannot be accomplished until there is one head for all navy and army aircraft work.

A very large percentage of the thousands of delays referred to in the sub-committee report are due directly to poor organization of the Aircraft Production Board in the past. The board was really a dual entity, in that the executive power rested with the army and navy representatives on it, whereas the civilian members only had advisory power.

While the civilian members may be indirectly blamed for the progress of the aircraft program to-day, the fact must be understood that these civilians were without the necessary power, and it is unfortunate that they took up the position and placed themselves open to criticism under such conditions. Credit must be given these civilians for making literal sacrifices under such a situation, because it can only be said that their intentions and motives were of the highest order.

The 1220 pages of hearings conducted by the sub-committee bear out the fact that in army circles there was a decided lack of co-operation and desirable understanding, particularly between those in Europe and those at home.

General Kenly made the point quite clear in his evidence that orders from France given for one kind of plane were countermanded a few days later. Sometimes the countermand came some months later. This was true with the Spad order given to Curtiss, which was given at the direction of the military authorities in France, and which was later countermanded by these same authorities on the ground that the Spad was at that time an obsolete machine; yet it is to-day one of the best chasse or fighting types, and we are now proceeding with orders for the construction of a British type similar to the Spad.

The aircraft authorities in this country took their entire advice from the military authorities in France on this subject.

This is not cited as a criticism of the military authorities, but rather as an example of how necessary it is to have a single head for the entire aircraft task; and further, how necessary it is to have the closest unity between France and America in this work.

Another example of the lack of co-operation between the military and civilian members of the Aircraft Production Board was that the civilian members gave the go-ahead order on one type of bombing plane so that production could be started last fall, but it was months before the go-ahead order was executed by the military authorities.

No reason is given for the delay, but it is evidence of how necessary it is to have one-man control instead of having civilian members going over a certain task and making recommendations, and then apparently having more valuable time consumed by army or navy members going over the same field and several months later coming to the same conclusion.

The lack of one-man decision was also shown in the Liberty engine program, which was originally planned as an eight-cylinder design, and the development started as such, but changed to a twelve-cylinder design last fall under recommendations from France. Now that the twelve-cylinder design has been developed, it proves to be too powerful for the De Haviland 4 plane, which was adapted to its use. It seems that less power is actually needed for this two-man machine.

A one-man scheme of organization would have unquestionably prevented a great many delays and misunderstandings which have arisen due to the apparent failure of different factions to co-operate as they should have. There has been a serious delay and a slow program on the development of planes to meet engine requirements. Whether this has been due to holding off until the Liberty engine was thoroughly developed and its suitability for different types of planes ascertained, is not certain. It does appear that our bombing program is sadly delayed, part of which has already been explained.

We cannot but again refer to an editorial in these columns some months ago, in which it was recommended that more engineers be literally conscripted into the airplane engineering program, and that a corps of these be maintained as close as desirable to the combat field in France, and that the speediest courier service between those engineers and those at home be maintained.

The development of a complete airplane program is so enormous that no small group of engineers can possibly handle it. The work of differentiation is so wide that a corps of engineers with highly varying qualities is needed.

It is unfortunate that the automobile industry is so generously blamed for the present situation in the aircraft program. The report insinuates that there are other manufacturers in the country that could have handled the work to better advantage. This seems to be the one case in—*Continued on page 391.*

# □ Latest News of the

## Five Types of Planes Under Test

Include SE5, Bristol, De Haviland and Two Others—Pomilio Built in Indianapolis

WASHINGTON, Aug. 28—The SE5 plane, stated Mr. Ryan to-day in answer to an inquiry by a representative of AUTOMOTIVE INDUSTRIES, is still being used by British airmen. He would not comment on the fact that it has been replaced by four machines, each superior to the other in turn. Mr. Ryan also stated that we are adopting the latest Bristol, although the foreign experts report to the contrary.

"Liberty twelve-cylinder engine production," said Mr. Ryan, "is fully up to expectations. Orders for them have been increased from 22,000, which were ordered prior to last May, to 50,000. A large quantity of the Liberty eight-cylinder engines and also of the 150 hp. and 300 hp. Hispano-Suiza have been ordered. The eight-cylinder Liberty engine, which is a 250 hp., and the 180 hp. Hispano-Suiza are in quantity production. The 300 hp. Hispano-Suiza will soon be in quantity production."

We are now trying out five types of planes new to this country at Dayton, according to Mr. Ryan. These include the SE5, the Bristol exactly as made in England, a two-seated fighter plane especially designed for the Liberty engine by an ex-captain, and two other types which Mr. Ryan refused to discuss. All of these planes, he said, can be put in quantity production if they are found satisfactory.

Members of the Pomilio family, together with 30 designers and workmen, have just arrived in this country from Italy to work for the Department of Aircraft production in designing new planes, said Mr. Ryan. The Pomilio have sold their Italian airplane interests to the Ansaldo Co. The Pomilio organization will be located at Indianapolis. Mr. Ryan pointed out that the Government is using the services of every first class airplane designer in the country and mentioned such men as Glenn Curtiss and Glenn Martin and said all men of their standing are receiving every encouragement from him.

He stated that the changes in the De Haviland 4, as ordered by General Pershing, have previously been recommended by a representative of the original aircraft board who had been sent to England to observe the English manufacturers build the De Haviland 4 over there and will return to this country and file

a report just prior to General Pershing's.

Mr. Ryan also cited an American officer lately returned from France, who stated that the De Haviland Company itself is enthusiastic over the American De Haviland design.

He told this in refutation of the testimony of army officers and others who claimed that the De Haviland 4 is a dangerous machine to fly and is inefficient because it has been changed considerably in mechanism and structure. There has been no let-up in the De Haviland production, said Mr. Ryan.

Airplane engines, he said, are the real limiting factor in the air programs of all warring countries and we are therefore concentrating on engine production, not only to meet our own needs, but also to meet the demand of the allies who are clamoring for far more Liberty engines than we can produce.

### Order 8000 Liberty Eights

DETROIT, Aug. 29—Special to AUTOMOTIVE INDUSTRIES—Dispelling all doubt regarding the purposes of the Aircraft Board in so far as the eight-cylinder Liberty engine is concerned, announcement has been made that contracts for 8000 of these already have been let. Of this total, the Willys-Overland Co. will produce 3000 in the Curtiss plant and the other 5000 is to be made by the Buick Motor Co.; production on both orders will be started soon. The Willys-Overland company is at present devoting fully two-thirds of its capacity to war work. The Elmira plant is 90 per cent on war work and the Elyria plant 75 per cent. The production of 8-in. shells will start next week in the new Toledo plant and the production of gun carriages has been started in another new plant. The passenger car output is now 300 cars daily. The production of the Curtiss company is now 800 planes monthly.

### Redfield a Member of Priorities Committee

WASHINGTON, Aug. 27—William C. Redfield, Secretary of Commerce, was to-day appointed a member of the Priorities Committee of the War Industries Board. His appointment is regarded as distinctly advantageous to industries classed as non-war. Last week Secretary Redfield declared himself in favor of giving more attention to the so-called non-war industries, so that their organizations and factories will be kept intact for after-the-war trade.

It is reported that thousands of complaints have been made to official Washington recently against the shutting down of factories not producing war materials. Secretary Redfield favors priority rulings which will permit limited operation.

## Ryan Heads Army Air Service

Appointed Second Assistant Secretary of War in Charge of All Army Air Activities

WASHINGTON, Aug. 28—John D. Ryan, director of the Bureau of Aircraft Investigation, has been appointed Second Assistant Secretary of War in charge not only of aircraft production but also of all military aeronautic activity. Major General William Kenly, head of the Department of Military Aeronautics, will hereafter report to Mr. Ryan. A new head of the Bureau of Aircraft Production will be named shortly by Mr. Ryan. Until the new director is named, W. C. Potter, assistant director of the bureau, will be the acting director, according to a statement made to-day by Mr. Ryan.

This consolidation of all military air activities under one head by Secretary Baker with the concurrence of the President virtually establishes an air ministry in line with the recommendations of the Senate Military Committee but with less powers than that committee desires.

The Senate Committee demanded a separate section to be controlled by a secretary of aeronautic operations, who was to be placed in supreme command, responsible only to the President. Under the new arrangement the army air service still remains a subsidiary of the War Department and Mr. Ryan is responsible to both Secretary Baker and President Wilson, while the naval air service remains under Captain N. E. Irwin, United States Navy.

Opinions expressed by both military and naval authorities are not in favor of a co-ordination of naval and military air operations. It is pointed out that our naval air program is radically different, involving questions of navigation and co-operation with the navy. Both Secretaries Daniels and Baker coincide with this view.

### Financial Aid for Non-War Industries

WASHINGTON, Aug. 29—Financial aid will be afforded to all non-war industries suffering serious curtailment if a plan proposed to-day by Bernard M. Baruch, chairman of the War Industries Board, becomes effective. Mr. Baruch has pointed out to the Federal Reserve Board that all of the non-war industries requiring material which is needed for the war must be "skeletonized" and asks that financial aid be given to save them from being wrecked. The Federal Reserve Board is considering the suggestion.

# Automotive Industries

## Cut Car Production to 25%

### War Industries Board to Allow Makers to Produce 50% During Remainder of Year

WASHINGTON, Aug. 26—Passenger-car manufacturers will be given steel sufficient to balance their inventories for a production, during the last 6 months of 1918, equal to 50 per cent of the production in the same period of 1917. Those makers who have more steel than this figure allows will turn over their excess supplies to other automobile factories which need it to complete their production.

The makers are further pledged to purchase no materials, equipment or supplies other than those needed to absolutely match up the stocks on hand. Upon meeting these conditions the manufacturer's requests for steel will receive preference treatment from the Priorities Division of the War Industries Board.

### Urge 100 Per Cent War Work

No decision has been made regarding further supplies of steel to the industry following Jan. 1, 1919, but the board in its letter to the National Automobile Chamber of Commerce, setting forth the above, again urges the industry to use all possible haste in averting the plants for use in either direct or indirect war work.

These decisions by the War Industries Board are the results of meetings between the board and Hugh Chalmers and Alfred Reeves, representing the industry. The agreement finally arrived at by the board was expressed in a letter sent to the N. A. C. C. and signed by Alexander Legge, Edwin D. Parker, J. L. Replogle and George N. Peek

### Inventories Aggregate \$150,000,000

The letter points out the fact that the inventories of raw materials and semi-finished materials in the hands of the industry aggregate \$150,000,000, and that these cannot be liquidated without additional supplies of steel which will allow the makers to match up the various parts.

The magnitude of the industry, which had more than \$1,000,000,000 in 1917, was one of the primary considerations which influenced the decisions of the board according to the members. They stated that they believed that an industry of this size was entitled to all the assistance that could be legitimately given in enabling it to clean up its stocks.

Following is the full text of the letter sent to the N. A. C. C.:

National Automobile Chamber of Commerce,  
7 East 42nd Street,  
New York City.

"Supplementing our letter to you of the 9th instant we beg to advise that we have now received most of the reports embodying the data and information which we requested you to furnish us, and have given these reports careful study and consideration. From them it appears that the stocks of raw materials and of semi-finished materials in the hands of manufacturers of passenger automobiles, while large, are greatly unbalanced, with the result that these large stocks, aggregating approximately \$150,000,000, cannot be liquidated until they have been 'matched up' with other materials necessary to manufacture the completed cars.

"The conclusion has been reached that it is in the public interest, as well as in the interest of your industry, that it be assisted as far as practicable, without interfering with the war program, in the liquidation of its stocks now on hand; and to that end the Priorities Division of the War Industries Board will accord a degree of preference designed to accomplish this result, to all manufacturers of passenger automobiles who will subscribe to a pledge to be prescribed by the Priorities Commissioner embodying in substance the following:

"(1) That the manufacturer will limit its purchase of materials, equipment and supplies to such as are absolutely necessary to match up its stocks now on hand.

"(2) That its production of passenger automobiles, and all repair parts therefor, shall not for the six months ending with December 31st, 1918, exceed 25 percent of its production for the calendar year 1917.

"(3) That it will conserve and economize in every possible way its stocks of iron and steel and their products now in its hands, or that may come into its possession, and will release on request of the War Industries Board to such other manufacturer of passenger automobiles as may be designated by the said Board such of its stocks as can be utilized by such other manufacturer and which are not required by it for either the limited production above specified or for war work.

"(4) That it will from time to time render such reports of its activities under oath or otherwise as may be called for by the War Industries Board.

"The War Industries Board will in carrying into effect the terms of the pledge herein provided for use as a basis, as far as applicable, the sworn reports recently rendered it in pursuance of its request.

"In justice to the passenger automobile industry we feel again impelled, as the situation appears to us now, to frankly repeat our statement to you of August 9th, that the urgent war requirements for iron and steel are so great that the probability of your industry procuring iron and steel after January 1st, 1919, for the manufacture of passenger automobiles is so uncertain that we again urge the members of your industry to as rapidly as possible utilize your facilities for the production of direct and indirect war requirements, not only in the interest of the Nation but in the interest of your industry itself. In such effort the members of your industry will have the active and whole-hearted cooperation of this Board."

## Gas Conservation Requested

### Fuel Administration Urges Owners to Eliminate Sunday Motoring East of Mississippi

WASHINGTON, Aug. 28—Owners of passenger cars in States east of the Mississippi are requested to refrain from operating of their machines on Sundays by the Fuel Administration. Motor boating and motorcycling for pleasure are also barred. No mandatory order has been issued as yet. Owners are expected to voluntarily observe the request, which is effective beginning Sunday, Sept. 1. The request includes taxicabs. Exceptions are as follows, and include only motor vehicles used for necessary purposes:

Tractors and motor trucks employed in actual transportation of freight.

Vehicles of physicians, used in performance of professional duties.

Ambulances, fire apparatus, police patrol wagons, undertaker's wagons, and conveyances used for funerals.

Railway equipment using gasoline.

Repair outfits employed by telephone and public service companies.

Only voluntary compliance with the letter and spirit of the request will prevent the issuance of a mandatory order prohibiting the use of gasoline on Sundays, says the Fuel Administration. Nearly 3,000,000 automobiles, it is estimated, will be affected by the order, and it is expected that 9,000,000 gallons of gasoline will be saved each Sunday if the request is strictly observed. Dr. Garfield made it plain to-day that the Government believes automobile owners will observe the spirit of the request and that issuance of a mandatory order will not be needed.

The heavy demand for gasoline overseas for use in airplanes, tractors, tanks, trucks, passenger cars and motorcycles is the principal cause for this conservation measure, while, in addition, there is the large and constantly growing demand for fuel oil for many of the war machines. Heretofore by cracking processes it has been customary to take one barrel of gasoline from two barrels of crude oil. Owing to the exceedingly large demand for fuel oil this proportion is being reduced, and it is likely that shortly only 30 per cent of each barrel will be made to yield gasoline. While the stocks of gasoline and oils are always low at this time of the year, up to this year production has been slightly in excess of the demand. In July of this year, however, consumption was 29 per cent

(Continued on page 400)

## St. Louis Develops Return Loads

### Chamber of Commerce Traffic Department Distributes Useful Data

ST. LOUIS, Aug. 24—Under the leadership of the traffic department of the Chamber of Commerce the return loads bureau is making definite progress. During the last week P. W. Coyle, of the Chamber of Commerce, has sent to local shippers a letter giving the data concerning time-tables and warehouse facilities of five truck lines to towns 20 or more miles distant from St. Louis. A meeting has been called for this week, at which bills of lading and rate data will be discussed by the express line owners and managers of local truck companies.

It has been developed that the chief drawback to shipments by truck lines has been the failure to observe the time card. Also that the chief fault with a return load from the smaller city was the failure to maintain a warehouse where a bill of lading could be issued. These defects can be remedied.

H. R. Brashier, assistant to Traffic Commissioner Coyle, has taken up the warehouse work. It is expected that several of the St. Louis warehouses will be consolidated. Country produce off the Missouri side of the river and coal on the Illinois side have been offered for return loads.

At the last meeting W. F. Rehbein, branch manager here for the Garford Motor Truck Co., was chosen chairman of the Joint Interurban Motor Truck Service Committee.

### Limited Supply of Coal for Michigan Passenger Car Industry

WASHINGTON, Aug. 24—The passenger car industry in Michigan will be limited in bituminous coal storage to a 20-day supply to be delivered after preferential industries, which includes the motor truck industry, are given a 45-day supply. The industry in other states will be limited to a 15-day supply after preferred industries receive a supply from 20 to 30 per cent. Public utilities will receive supplies ranging from 30 to 90 days before the non-preferred industries are supplied. All non-preferred industries are completely cut off from future shipments of by-products and gas coal.

Coal in excess of the above storage limitations, which are considered sufficient for current operations, will not be delivered to non-preferred plants for use before April 1, 1919, unless there is a surplus over the demands of the preferential consumers.

### Studebaker Gun Carriage Christened

DETROIT, Aug. 24—Over 2000 munition workers of the Studebaker factories, 250 of whom were women in shop overalls, celebrated in fitting style the

christening of the first of the many siege gun carriages which they will turn out during the next few months. The carriage was christened "Black Jack."

### American Import Restrictions Affect Ceylon Plumbago Output

THE plumbago industry in Ceylon is experiencing a period of stagnation, due chiefly to decreased shipments of graphite to the United States. Although the War Trade Board's restriction on plumbago imports has been a factor in this stagnation, there was a lessened demand on the part of American importers several months previous to the American restriction becoming effective. It is noted, for instance, says Consul Walter A. Leonard, that the plumbago shipped to the United States from Ceylon during the quarter ended March 31, 1918, totaled only 2194 tons, valued at \$405,064, according to invoices certified at this consulate, as against 6524 tons, valued at \$2,166,957, during the corresponding quarter in 1917.

In 1917 the United States took over 81 per cent of Ceylon's plumbago as compared with 75 per cent in 1916 (percentage based on quantity, not value), showing how dependent the industry is on the American market. The year 1917 was not quite as prosperous for the plumbago industry as the record year of 1916, when the total quantity exported was 668,216 hundredweight of 112 lbs., valued at \$7,298,128, as compared with 540,950 hundredweight valued at slightly less than \$6,500,000 in 1916. While the best grades of plumbago sold for as high as \$500 per ton during 1916 and 1917, half this price is not obtainable at present.

Unlike the tea and rubber industries, plumbago mining is largely in the hands of native Ceylonese, the majority of owners being men of small means with labor forces not usually numbering more than 20. Such owners must rely on an immediate sale of their graphite, and any marked fluctuations in the market will cause them to shut down or open up their mines. Thus it is observed that on June 30, 1917, when the market was good, 1288 mines were being operated, and employing 19,912 men, as compared with 764 mines at the end of the year employing 15,379 men. The small mines are obviously the ones first shut down in case of market depressions.

In 1916 the total output of Ceylon's graphite mines was over 33,000 long tons (of 2240 lbs.), compared with approximately 26,000 tons in 1917. Improved machinery, especially in working mines to greater depths, should enable Ceylon graphite to be mined at approximately the rate of 30,000 tons annually for many years to come.

### Puritan Buys Broc Electric Parts

DETROIT, MICH., Aug. 24—The entire stock of parts for the Broc Electric, formerly made in Saginaw, Mich., has been bought by the Puritan Machine Co., of Tenth and Lafayette Avenues.

## Location for Ford Mexican Plants

### One Factory to Be at Monterey and Another Plant at Guadalajara

MONTEREY, MEXICO, Aug. 26—Locations for two of the proposed tractor manufacturing plants which Henry Ford plans to construct in Mexico have been tentatively selected and only await the formal approval of the Carranza Government for final decision. One of the plants is to be located at Monterey and the other one at Guadalajara. It is stated that the project embraces also the establishment here of a large automobile assembling plant. In the contract entered into between Mr. Ford and the Mexican Government it is stipulated that all of the raw materials and finished products entering into the manufacture of the tractors and automobiles shall be of native production. No difficulty will be experienced in complying with this requirement, it is expected. Steel may be obtained from the plant of the Monterey Iron & Steel Co.; timber is available in abundance; cotton and other fibers may be had for fabrics.

### Exports to Holland and Denmark

WASHINGTON, Aug. 25—Passenger cars, bicycles, motorcycles and spare parts of these excepting tires and accessories will be considered for exportation to European Holland and Denmark proper by the War Trade Board, according to an announcement to-day. Prospective importers in European Holland must obtain import certificates from the Netherlands Overseas Trust Co., following which the importer must notify the prospective exporter of the serial number of the certificate. The exporter can then apply to the War Trade Board for an export license. This means that the shipments to European Holland, except those consigned to the Government of the Netherlands, must be consigned directly and only to the Netherlands Overseas Trust Co.

When importing merchandise to Denmark the importer must first obtain an import certificate from the Merchants' Guild of Copenhagen or the Danish Chamber of Manufacturers and then advise the exporter in the United States of the serial number. The exporter in turn can then secure his license from the War Trade Board. In the case of Denmark, shipments may be consigned to an individual.

### Pennsylvania Rubber Declares Dividend

JEANNETTE, PA., Aug. 23—At a meeting of the board of directors of the Pennsylvania Rubber Co., held on Aug. 19, the regular quarterly dividend of 1½ per cent on preferred stock and 1½ per cent on common stock was declared, payable Sept. 30 to stockholders of record Sept. 15.

*Characteristic straight line body design is evident in the new Westcott*

## Westcott Arrowline Seven

**A New Model with Straight Body Lines and a Continental 9-N Engine  
—Standard Parts Are Used Throughout**

A new seven passenger model, known as the Arrowline Seven, has been announced by the Westcott Motor Co., Springfield, O. The body is of characteristic straight line design. The top line of the hood and cowl from the radiator to the instrument board is perfectly straight, and there is another straight line extending from the top line of the doors through to the radiator. The doors have sharp, square corners at top and bottom. The door handles are of tee design, with inside release, and the bumpers are of diamond bar shape.

This body is mounted on the standard Westcott six cylinder chassis, with a wheel base of 125 in. Cantilever springs are used at the rear, which combination permits of the use of a long body. The seats are pitched at an angle for comfortable riding, and the upholstery is very soft and deep. There is plenty of foot room for all of the seven passengers.

The front seat of the car is undivided, thus affording space for an additional passenger in an emergency. Between the disappearing seats in the rear is a small compartment for personal effects, which are secured against theft by a Yale lock, controlled by the same key as the ignition switch. Above this compartment swings a robe rail of leather. Tonneau and cabinet are illuminated by a small electric light. The instrument board is of walnut, and an unusual item of equipment is an electric signal lighter with extension cords.

The new Westcott is equipped with the Continental 9 N engine, of 3½ in. bore by 5½ in. stroke. Standard parts are used throughout the chassis, including the Delco starting, lighting and ignition system, the Rayfield carburetor, Gemmer steering gear, Fedders radiator, as well as oil cup lubrication, self acting top and thermostatic control of the temperature.

### U. S. Light & Heat Corp. Elects Officers

NIAGARA FALLS, N. Y., Aug. 23—At the annual meeting of the stockholders of the U. S. Light & Heat Corp., held at the offices of the company, the

following directors were elected for the ensuing year:

Ralph C. Caples, Egbert H. Gold, Edwin K. Gordon, James E. Kepperly, Chauncey L. Lane, C. O. Mininger, James O. Moore, B. J. O'Reilly, James A. Roberts, George G. Shepard and J. Allan Smith.

The following officers were elected for the ensuing year:

Egbert H. Gold, chairman; J. Allan Smith, president; Chauncey L. Lane, vice-president and general manager; B. J. O'Reilly, treasurer; R. H. Van Nest, secretary; T. G. Swannie, assistant secretary and assistant treasurer.

### Maxwell Motor Co. Calls Special Meeting

DETROIT, Aug. 26—A special meeting of the stockholders of the Maxwell Motor Co. has been called for September 5 for the purpose of considering and acting upon resolutions expressing the election of the company to have the moneys held by the Central Union Trust Co. applied to the purchase of shares of the first preferred stock for retirement.

### Gutta-Joolatong Rubber May be Imported

WASHINGTON, Aug. 24—Importation of gutta-joolatong rubber which has been prohibited by the War Trade Board is now allowed to the extent of importing a limited amount necessary for essential purposes in this country during the remainder of the calendar year. The amount licensed for import will be allocated by the Bureau of Imports of the War Trade Board among manufacturers in accordance with their requirements for the production of commodities essential to the success of the war.

### More Roads for Colorado

DENVER, Aug. 23—Plans for extensive development of Colorado highways, promotion and regulation of motor truck transportation and a general advancement of the motor car industry in this territory have just been decided upon

*Interior of Westcott Arrowline Seven*

at a Denver meeting of the executive committee of the Colorado Good Roads Association and the legislative committee of the Colorado Association of County Commissioners. The four main steps to be urged by a statewide campaign are:

(1) An enabling act to give the people of the state an opportunity to vote on a bond issue for building and maintaining permanent highways throughout Colorado.

(2) A transferring from the general fund to the state highway fund of all receipts from the state inheritance tax, now amounting to about \$150,000 yearly.

(3) A doubling of the yearly motor car license fees, which are now far below those in effect in many states.

(4) State traffic regulations aimed to give control over the speed of motor trucks, width of tires and other factors vitally affecting the wear of highways.

### Want Tractor Exhibits in N. E.

BOSTON, Aug. 24—Efforts are being made to develop tractor sales in New England. Plans are under way now to try to get some interest aroused to have tractor contests at some of the numerous county fairs throughout New England in the fall. No section has a greater number of fairs for its size than the six states comprising the group up here.

### Conveyor Increases Tractor Production

DEARBORN, MICH., Aug. 23—Henry Ford & Son have completed the installation of a conveyor in the plant in which final assembly is made. With the aid of this production has jumped upward and the daily output is now averaging 160. The production last week was 919 tractors as compared with 835 the week previous.

### Liberty Gets Government Order

DETROIT, Aug. 24—The Liberty Motor Car Co. has received an order from the Government for 2500 two-wheel trailers similar to those the Paige-Detroit Co. is working on. The company's production of passenger cars for last month was 250, and is averaging 10 a day at present.

## Makers of Wheels Organize

### Form Association of Automotive Wheel Manufacturers for Co-operation

TOLEDO, Aug. 28—The Association of Automotive Wheel Manufacturers was formed in this city a few days ago when twelve concerns, representing practically all the makers of metal wheels and some of them representing wood wheel interests, met for the purpose of organization. The complete scope of organization has not yet been decided upon, but has been left to a committee of three, which will draft plans and present a report at the next meeting of the manufacturers' interests which will be held in September, perhaps in this city. The committee of three to carry out the organization is made up of Mark Merriman of the Hayes Wheel Co., H. A. Coffin of the Detroit Pressed Steel Co., and George L. Lavery of the West Steel Castings Co. The conception of the Association of Automotive Wheel Manufacturers dates back to 1917, when Washington had some misconception of the possibility of metal wheel manufacture and when it was assumed that the metal wheel production was limited to foundry capacity, whereas its limitation was confined to machine shop capacity. It was this misconception on the part of the Government which led manufacturers to see the necessity of co-operation in order that the wheel problem might be correctly presented where necessary.

The objects of the association are to investigate the promotion of engineering connected with wheel manufacture and also the mechanical problems connected therewith. The necessary research and investigation into various lines of automotive manufacture is also one of the spurs to action. Undoubtedly many problems relating to standardization will be considered by the association, not that it will pass upon the standardization work but rather that closer co-operation with the Society of Automotive Engineers can be carried out. The association has in mind the more complete co-operation of all makers in the field and the welding together of all interests. Among those present were:

A. H. Anthony, Massillon Steel Casting Co.  
Edward H. Webb, Dayton Steel Wheel Co.  
Geo. L. Lavery, West Steel Casting Co.  
G. S. Porter, Hayes Wheel Co.  
Mark Merriman, Hayes Wheel Co.  
Ralph D. Webster, Wire Wheel Corp. of America.  
R. F. Flinterman, Michigan Steel Casting Co.  
Geo. Walther, Dayton Steel Foundry Co.  
R. P. Flower, Standard Steel Casting Co.  
A. L. Jelley, All-Steel Wheel Co.  
W. E. Burns, Michigan Malleable Iron Co.

Replies from those favorable to the formation of an organization who were unable to attend were read from the following:

B. L. Smith, Smith Wheel Co.  
Edward Budd, Budd Wheel Corp.  
Isaac G. Johnson & Co.  
Bertner Fleeger, Stryer Steel Casting Co.

### Hanks Leaves S. A. E.

NEW YORK CITY, Aug. 28—M. W. Hanks, who has for over a year had charge of the standardization work of the Society of Automotive Engineers, has resigned, and connected himself with the navy as mechanical aeronautical engineer. It is in connection with standardization work in the navy that Mr. Hanks hopes to carry on the work he has been connected with in the past.

### New Aviation Training System Adopted

WASHINGTON, Aug. 27—Experienced flying officers are now being returned from abroad to act as special instructors in the advanced courses of aviation training. Candidates for flying service consequently receive more individual training in this country. A new plan, known as the Gosport system, or "All Thru," as it is, popularly called here, is used, which brings closer contact between the cadet and the instructor. When the cadets arrive at a flying field from the ground school, where they have learned much of the theory of flight, engine control and repair, radio, signaling, and other kindred subjects, several of them are assigned to an instructor, who stays with them until they have qualified in elemental flying. They are then sent to the special schools for final work, and training in their particular line, as pursuit, reconnaissance, artillery control, or bombing pilots. The old practice of giving a cadet so much time in the air under instruction, and then turning him loose for his first solo flight, in a "sink-or-swim" fashion, is being discontinued, and what is believed to be a more safe and sane system is being adopted.

### Aviation Field Accidents Show Decrease

WASHINGTON, Aug. 27—Six deaths resulted at aviation fields in this country for the week ended Aug. 17. This represents but one fatality for every 3638 hours flown, or 291,040 miles of air travel. Following is the summary:

Brooks Field, San Antonio, Tex..	1
Carlstrom Field, Arcadia, Fla....	1
Carruthers Field, Benbrook, Tex..	1
Kelly Field, San Antonio, Tex....	1
Chanute Field, Rantoul, Ill.....	1
Post Field, Fort Sill, Okla.....	1

Total..... 6

### Hart-Parr Dynamometer Performance

CHARLES CITY, IA., Aug. 26—The Hart-Parr Co. has given out the results of the dynamometer test on its 30-hp. tractor at the Salina demonstration. According to the official report, signed by Oscar W. Sjogren and C. K. Shedd, engineers in charge, the engine of the tractor gave an average output of 31.13 hp. at an average speed of 731.8 r.p.m. for a period of 30 min. According to A. W. Fitzpatrick, service manager of the company, the test was made at 12.30 p. m., when the Government thermometer was at 109 deg. in the shade, yet the temperature of the cooling water never rose above 175 deg.

## Government Schools in Employment

### Organizes Instruction Classes to Train Executives Without Charge

WASHINGTON, Aug. 26—The Government has organized a system of War Emergency Courses for the training of employment managers which has involved the creation of an advisory committee to set the general standards of instruction with the co-operation of a number of departments at Washington. These include the Ordnance Department, the Quartermaster Department, the Navy Department, the Department of Labor, the Emergency Fleet Corporation, the General Staff and other Government divisions. The policies of this committee are carried out by a staff organized as the Employment Management Division of the War Industries Board.

This division has secured the services of the foremost instructing authorities of the country on each individual subject dealt with. The subjects included in the course cover the organization and equipment of an employment department, the employing of the worker, training the worker, payment, control of working conditions, keeping the worker up to standard, the government of the shop, etc.

The means of instruction include systematic lectures by experienced teachers who will devote all their time to the work, and special lectures by experts who have had practical experience in specific lines. These are supplemented by studies made in efficient plants and other illustrations of given conditions.

To these courses employers are invited to send men or women of their own choosing, subject to the approval of the division. It is, of course, understood that those benefiting by attendance will return to their sponsors and be utilized by them in employment work.

Instruction is, in all cases, offered without any charge for tuition. The only outlay is for the living expenses of students while in residence and about \$15 for books and supplies. Application for admittance to any of these courses should be sent to Captain Boyd Fisher, 717 Thirteenth Street, N.W., Washington, D. C., who will furnish the necessary blanks, etc.

The following courses have been arranged and others will be announced later:

City	School	Date
Boston, Mass.....	Harvard, Boston University and Massachusetts Institute of Technology co-operating	Sept. 2
Rochester, N. Y..	University of Rochester	Sept. 16
Pittsburgh, Pa....	Carnegie Institute of Technology and University of Pittsburgh co-operating (tentatively)	Sept. 23
New York, N. Y..	Columbia University	Sept. (date not yet fixed).

Courses will follow at about eight-week intervals at each of these schools.

## Imports of Rubber Drop Slightly

July Is 1198 Tons Behind Last July—Total for 6 Months Is 10,189 Tons Ahead

NEW YORK, Aug. 26—Importations of crude rubber dropped slightly during the month of July as compared with the previous month, though the total for the first six months of the year is well in excess of the total for the first six months of 1917. During July, 1918, a total of 16,092 tons was brought in, as compared with 17,290 tons in July, 1917, the drop amounting to 1,198 tons. July, 1918, showed a much greater drop when compared with June, the difference being a loss of 8022 tons.

During the first six months of 1918 the total amount of rubber brought in was 105,371 tons. This compares with 115,560 tons brought in during the first six months of 1918, making this year to date 10,189 tons ahead of last year. Following are the statistics as compiled by the Rubber Association of America:

Months	1917, Tons	1918, Tons
January .....	12,788	16,084
February .....	10,162	13,108
March .....	18,624	17,161
April .....	13,000	12,703
May .....	18,411	16,288
June .....	15,096	24,124
July .....	17,290	16,092
Total .....	105,371	115,560

### Export of Tin Plate Regulated

WASHINGTON, Aug. 26—New regulations (W. T. B. R. 209) have been published by the War Trade Board governing the issuance of licenses for the exportation and manufacture of tin. Applications for licenses to export tin plate will only be received from the manufacturer, or, if the applicant is other than the manufacturer, when evidence satisfactory to the War Trade Board shall be furnished showing that the purchase of the tin plate to be exported has been made by the applicant directly from the manufacturer. A copy of the contract for such purchase shall be filed with the application.

Of more direct interest to concerns in the automotive and allied industries are the conditions governing the issuance of licenses for the exportation of bearing metals, anti-friction metals, white metals and tin alloys containing more than 5 per cent of tin; of solder containing more than 40 per cent of tin, and of tin foil, collapsible tin tubes, bottle caps or covers of tin foil containing more than 5 per cent of tin.

Applications for such licenses will be considered provided that, in the case of shipment to Canada or Newfoundland, evidence satisfactory to the War Trade Board is furnished showing that the

above-mentioned commodities are to be used for a purpose for which they may be used within the United States, and do not contain a percentage of tin higher or of a quality other than is requisite for the purpose to which they are to be put.

If the shipment is to other destinations, evidence must be furnished that it is intended for a purpose which will contribute directly to the successful prosecution of the war, and that the tin content of the bearing metals and solder does not consist of Straits tin or Banca tin.

If the tin content of the various alloys is less than given above, consideration of the application will be facilitated if it is accompanied by an affidavit from the manufacturer stating the amount of tin content.

### Ford to Produce Thousands of Whippets

DETROIT, Aug. 26—The Ford Motor Co. has begun production of thousands of Whippet tanks of the small type for the Government, for which it has been awarded a contract amounting to millions of dollars. The Ford company has been experimenting for some time with the small tanks similar to those which recently achieved success on the western front, and is now in a position to manufacture them on a large scale. Before the contract was received, officials of the company stated that small tanks could be turned out with nearly as great rapidity as Ford cars, and it is expected the daily output of tanks will be extremely large. The exact size of the contract is not stated, but it is reported to be one of the largest received in Detroit.

### Railroads Largest Steel Users

WASHINGTON, Aug. 23—A meeting yesterday between the War Industries Board, Dr. H. A. Garfield, Fuel Administrator; Carle Gray, representing the Railroad Administration; Felix Frankfurter, of the Department of Labor, with the War Service Committee of the Iron and Steel Institute and other steel makers, showed that the largest Government agency consuming steel is the railroads; next, ship builders; third, War Department, and fourth, the Navy Department. Discussion as to the best means of meeting these actual war requirements without possibility of curtailment resulted in decisions that there must be:

1. Greater conversion of mills to the production of steel that is required in the war program.

2. An increase in the coal supply, particularly by-products coal, available for mills engaged on Government work.

3. Shutting off further steel shipments to industries other than those engaged in meeting war needs.

4. More rigorous conservation in the handling of steel in the mills.

The steel men in the meeting promised to co-operate to their utmost in meeting the Government's steel requirements and virtually pledged themselves to so increase their output as to guarantee the needs of the war program.

## Order 17,000 Class "A" Trucks

White, Packard, Peerless and Pierce-Arrow to Build Standardized White Trucks

WASHINGTON, Aug. 26—Following last week's announcement in AUTOMOTIVE INDUSTRIES of the reorganization of the motorized vehicle section of the army under the direction of the original regime which favored the standardized truck program, the following list of truck contracts has been made public. These contracts were made shortly before the reorganization took place and while the Motor Transport Service was under Col. F. M. Glover. The contracts were as follows:

White Co., Cleveland, 8000 "A" (White) 1½-ton trucks.

Peerless Motor Car Co., Cleveland, 3000 "A" (White) 1½-ton trucks.

Packard Motor Car Co., Detroit, 3000 "A" (White) 1½-ton trucks.

Pierce-Arrow Co., Buffalo, 3000 "A" (White) 1½-ton trucks.

These "A" trucks which were contracted for are the White 1½-ton trucks which were substituted for the original standardized "A" truck following tests held by Col. Glover together with the Ordnance Department.

These manufacturers have been allowed a price of \$2480 each for the trucks, and the Peerless, Packard and Pierce-Arrow companies have been allowed an additional \$100 for each truck for tool costs.

Col. C. B. Drake, whose nomination for Brigadier-General has been made, is already in active charge of the new Motor Transport Corps and Colonels Glover and George have been transferred to other army divisions. Col. Drake is at this time working out the organization of the new corps.

### Saxon to Make AA Trucks

DETROIT, Aug. 26—The Saxon Motor Car Corp., Detroit, has received a sample of the 1-ton truck of the Class AA type and will start shortly on the manufacture of a quantity of these trucks, for which an order was recently received from the Government.

### Milwaukee Wants Training School

MILWAUKEE, Aug. 26—Milwaukee, with thirteen large factories devoted to the manufacture of motors for passenger and commercial cars, trucks, tractors and aircraft, is making an effort to induce the War Department to locate a training school for automotive mechanics selected under the draft in this city. The Milwaukee County Council of Defense has been assured by each of the plants that they will assist in conducting and maintaining a school of this kind. It is pointed out that few cities in the United States have equal facilities for training soldiers in the construction, maintenance and repair of gas engines.

## Labor Shortage Shuts War Plants

Non-War Industries Must Furnish Help—1,000,000 Workmen Needed

WASHINGTON, Aug. 24—A shortage of 1,000,000 unskilled workers, and a tremendously increased shortage over this figure in the near future, is announced by the United States Employment Service of the Department of Labor. Reports show that some of the most important war factories have been forced to shut down units because of lack of labor. The Employment Service has notified all state directors that the 1,000,000 shortage of men must be met by securing the labor from non-war industries.

Nathan A. Smyth, assistant director general of the United States Employment Service, pointed out that if this labor demand is not met promptly the new army which will be raised by increasing the present draft age limit may be faced by lack of equipment. Mr. Smyth said:

"The figures now brought together show to what great extent a shortage of unskilled labor is imperilling the work of America's war industries. The seriousness of the situation can scarcely be exaggerated. Instance after instance is coming to our attention where the lack of unskilled labor threatens to cause some highly essential war project to close down.

### Available Labor Supply Depleted

"Though thousands of men have been moved by this service within the last 3 weeks, sometimes over great distances, we are confronted with the fact that available supplies of unemployed labor are practically depleted. Most of those who can now be found are of a restless, shifting type who will usually stay on the job only a little while, and are of slight value when there.

"As the army increases, the situation will grow more grave. The fact must be faced squarely and resolutely. There are plenty of men in the country to meet the present needs for unskilled labor, but they are now working at non-war work. The time has come when America must get fully on a war basis.

"If we are not to leave our armies in the lurch for the lack of munitions and supplies, every able-bodied man in the country will soon have to find work in some essential industry. Patriotic employers in non-war industries should take immediate steps to reduce their forces of men to an absolute minimum.

"An aroused public sentiment, which will brand as a slacker any man who willfully refrains from working at some productive job up to the full extent of his capacity, will be more effective than any laws or regulations.

"What, perhaps, is most needed in our war industries is an infusion of men who

will undertake to work as common laborers because of our country's need. Their presence will be an inspiration and example to those already at work and will go a long distance toward reducing the inefficiency and abnormal turnover of labor which exists at many important projects. Americans, like the English and the French, must learn that 'common labor,' when performed for one's country in time of war, is worthy of any man, whatever his prior position or experience."

In order to fill the present labor shortage, additional quotas of unskilled labor have been assigned to the various states, bringing the total to be supplied to 878,150, distributed as follows:

State Quotas to Fill Labor Shortage of 1,000,000 Unskilled Workers	
Alabama	4,050
Arizona	2,640
Arkansas	3,870
California	42,150
Colorado	10,120
Connecticut	16,340
Delaware	1,670
Florida	4,930
Georgia	6,070
Idaho	2,020
Illinois	78,670
Indiana	20,940
Iowa	11,350
Kansas	10,120
Kentucky	8,100
Louisiana	8,000
Maine	7,660
Maryland	14,340
Massachusetts	58,960
Michigan	24,110
Minnesota	18,390
Mississippi	2,200
Missouri	25,260
Montana	2,980
Nebraska	8,180
Nevada	1,580
New Hampshire	4,930
New Jersey	38,310
New Mexico	1,140
New York	169,140
North Carolina	4,310
North Dakota	1,850
Ohio	49,370
Oklahoma	7,570
Oregon	8,620
Pennsylvania	83,250
Rhode Island	9,420
South Carolina	2,820
Tennessee	6,780
Texas	14,260
Utah	4,140
Vermont	3,430
Virginia	8,980
Washington	22,180
West Virginia	7,570
Wisconsin	16,980
Wyoming	1,780

### Giant Plane from St. Louis

ST. LOUIS, Aug. 26—W. E. Workman, general manager of the Handley-Page Aeroplane Mfg. Co., delivered a talk here last week to members of the Chamber of Commerce at a luncheon in which he told of factories to be built in this country. Immediately after the luncheon a movement was started to raise \$50,000 to build a giant plane here to fly to the war zone, where it will be offered in service. Some progress has been made in raising the fund.

## New Physical Tests for Airmen

Medical Research Laboratory Employs Apparatus Giving Standard Examination

WASHINGTON, Aug. 24—All men who have won their wings in the United States Air Service are now required to pass a new heart, lung, ear and eye test to establish their physical and mental fitness when high in the air, and particularly to indicate at what heights they are in a condition to fly. Cadets receive a test before they finish their schooling; flyers are given these tests periodically to eliminate any whose physical or mental efficiency has become in any way impaired.

These tests are the result of study and investigation by the Medical Research Laboratory at Hazelhurst Field, Mineola, N. Y., whose staff has devised apparatus and determined upon a standard examination for classifying pilots.

To stay in the rarefied air at an elevation of 20,000 ft. for any length of time has been found to be a strain on even the most physically perfect. It has also been discovered that many of the most seasoned flyers cannot undergo the sudden quick changes in altitude, occasioned by diving and climbing, without physical deterioration. It was recognized as too great a risk to subject these men to actual flying tests, and so the medical laboratory at Hazelhurst Field undertook to devise some way of getting the same results by means of a ground test.

In the early tests the pilot was placed in a steel, airtight cylinder from which the air was gradually exhausted and then replaced, to simulate a flight into the rarefied air of high altitudes and back to earth, but to-day the pilot sits comfortably in the same room with his examiners. His nose is clamped so that he cannot breathe through it. Over his mouth is placed the breathing apparatus, which is connected by tubes with a tank of measured air and with instruments that record every breath he takes. The air is analyzed at various stages of the run. As fast as he exhales, the air is taken into a reservoir, where it is cleared of carbon dioxide, and then returned to the tank. Gradually he uses up the oxygen and thus air conditions of high altitudes are duplicated. The higher one goes up, the rarer the air becomes; just so with the man under test; after a certain time he has consumed an amount of oxygen which leaves the remaining supply just equal to the oxygen available at a certain altitude. Time takes the place of height in the test. "All the way up," so to speak, several specialists watch him—one his heart, pulse and blood pressure, one his eyes, and the others his responses to signals and observations. Records of his pulse and blood pressure are made every other minute. The eyes are tested every three minutes.

The man under test is kept fairly busy, just as he would be piloting a plane. Before him on a table is a bank of small electric lights, one or another of which flashes every five seconds. These he must extinguish as fast as he observes them and before they go out. He has but a few seconds. Below the lamps is a corresponding set of buttons which, when touched with a pointer held in the right hand, extinguishes the respective lights. The observers watch him constantly and check his errors or delayed actions.

Another instrument before him is an ammeter, which acts similarly to a speed dial on a plane, and, accordingly, in the test must be kept at a constant point. One of the examiners, out of view of the pilot, changes the pointer from time to time, and it is up to the pilot to rectify his dial by sliding his right hand along an instrument ar-

ranged to compensate for the change. These two duties keep his right hand pretty busy; his left arm is not used, as it has the blood pressure apparatus attached. He is also keeping a small electric fan motor at a constant speed, the variations in speed being indicated by changes in the hum of the motor; the corrections are effected by a foot treadle, similar to an accelerator on an automobile. His every movement is noted and recorded by the observers, who see if his heart, lungs and eyes accommodate themselves to the altitude.

As time goes on (and the test lasts for about 30 minutes), the pilot becomes a bit groggy or sleepy from lack of oxygen, just as he would at the corresponding altitude, and this condition becomes manifest in changes in the action of his heart, eyes, ears and brain. Along toward the end of his run he may let the motor slow down, forget the indicator entirely, or miss hitting the light buttons. But he is immediately released when his heart shows a strain or his pulse or respiration gets too far from the normal condition.

A few minutes after his release from the apparatus all signs of his recent fatigue pass away and he becomes normal again. But a very important record has been established, his future safety practically assured, and he himself feels that it would be absurd, in view of the facts shown by the tests, for him to try to fly out of his level. Where argument and theory did not convince some headstrong pilots before, they readily accept the inevitable when "shown" to-day.

There are now three classes of pilots; those few who can endure an altitude of over 20,000 ft. without undue fatigue are in class AA and are designated to fly pursuit planes when they reach the front, if they keep within the class in future tests. The men who can stand the work at 15,000 to 20,000 ft. are in class A; from 8,000 to 15,000 ft., class B, and those from the ground up to 8,000 ft., class C.

Future tests may show that some may be moved up a class, say from B to A, or that others may have to be moved down, both for their own good and the good of the service.

#### Electrical Apparatus and Supplies Classified as Essential

WASHINGTON, Aug. 22—The manufacturers of electrical apparatus and supplies will be classified as essential, according to a statement by the Priorities Commissioner to-day. Manufacturers of these commodities, however, will have to pledge themselves to limit their output to essential products and to insure that such products are devoted solely to essential uses as that term may be defined from time to time by the Priorities Division. The manufacturers will be relied upon to supervise their own industries and also the jobbers, distributors and retailers of electrical supplies. Jobbers of these commodities will be permitted to maintain reasonable stocks for sale to Government agencies, war industries and the civilian population, provided the jobbers will pledge themselves to rigidly restrict use of all stocks to solely essential uses and to reduce the jobbing and retail stocks to a minimum.

#### Traverse City Becomes Napoleon

TRAVERSE CITY, MICH., Aug. 26—The capital of the Traverse City Motor Car Co. has been increased from \$150,000 to \$500,000, and the name of the company changed to Napoleon Motors Co. Following are the new officers just elected: President, W. J. Chase; vice-president, C. E. Culver; secretary-treasurer, Frank Trude; chief engineer and general manager, K. W. Oswald; directors, the officers and J. W. Patchin, George H. Curtis and C. S. May. The company has been turning out 1- and 1½-ton trucks and three models of passenger cars.

## Vestibule Schools Meeting Needs

### Intensive Training in 100 Plants Overcoming Serious Skilled Labor Shortage

WASHINGTON, Aug. 23—The serious shortage of 250,000 skilled workers in this country is being met by the factory training school plan, which has often been referred to in AUTOMOTIVE INDUSTRIES, according to a statement by Samuel Gompers, Chairman of the Committee on Labor of the Council of National Defense. The factory training school plan has been adopted by more than 100 large concerns, each employing more than 300 people. It is estimated that 750,000 new skilled workers will be required by Jan. 1, and Mr. Gompers urges all employers to adopt the factory training school plan, which is being furthered by the Committee on Labor.

#### \$1,500,000 Yearly for Training

The 100 factories mentioned by Mr. Gompers are spending approximately \$1,500,000 a year in this business of intensive training of new workers. The training investment is not regarded as an expense as the training itself results in production which equals the production rate of the factory shops.

Outlining the work of the past year by the Committee on Labor, and the possibilities of increasing the numbers of skilled workers Mr. Gompers said that one year ago that section of the committee on labor of the Council of National Defense which has been instrumental in developing the training department or vestibule schools above noted recorded the following as its declaration of policy:

"The section on industrial training for the war emergency is concerned with industrial training only as a war measure. It is not concerned with vocational education in general. In all cases in the existing crisis shortage of labor must be met first by training operatives from allied trades who are unemployed and by advancing operatives of ability from lower to higher positions in the occupation itself. For instance, apprentices should be advanced rather than outsiders. It is possible that many sewing women will be without work, and many men in the building trades. For all such, new and fitting places must be developed where possible. Non-wage earners must not be trained to take places for which unemployed wage earners may reasonably be trained."

#### Aluminum Price Put at 33 Cents

WASHINGTON, Aug. 23—A maximum base price has been fixed on aluminum at 33 cents per lb. f.o.b. United States producing plants, for 50 tons and over, of ingot of 98 to 99 per cent. This price will be effective until March 1, 1919. It was approved by the President yesterday, following an agreement made

between producers of aluminum and the War Industries Board. Differentials for sheet, rod and wire and differentials for quantity, for grade and for alloys will remain those approved by the Price-Fixing Committee of the War Industries Board as effective from July 1, 1918.

These prices will be effective on deliveries made during the period from Sept. 1, 1918, to March 1, 1919, on contracts made during this period; and furthermore, the new prices will be effective on deliveries made during this period on existing contracts which specify that the price shall be that in force at the time of delivery. Deliveries made during the period of Sept. 1, 1918, to March 1, 1919, on other contracts will be at the price stated in such contracts, except that on existing "direct and indirect Government contracts" containing a provision that refund is to be made of the difference between the price stated in the contract and the "Government fixed price, if, as and when made," such difference shall be refunded on deliveries made during the period from Sept. 1, 1918, to March 1, 1919, on presentation of proper proof that the purchasing Government gets the benefit of the refund.

#### New List of Preferred Industries Being Formulated

WASHINGTON, Aug. 22—The War Industries Board is formulating a new list of preferred industries, which will be twice as long as the present preferred list, which contains 32 classes. The extension of the list is due to widely expanded war needs and pressing demands of civilian origin. This new list will be used as a key to the relative importance of all of the country's industrial enterprises. Each industry is being surveyed as to national needs and when the list is once established it will be maintained by a system of priority which will determine the use of the materials, facilities, fuel, transportation, labor and capital needed for them.

The War Industries Board is working with the War Finance Board in the creation of the new list.

An important point in this new list lies in the fact that it will be used as an indication of what constitutes war work. The War Department's "work or fight" ruling will be made by men who are engaged in any of the classes of the essential industries listed. The new table may be expected within a week.

#### Thirty-two Biggan Trailers Daily

CORUNA, MICH., Aug. 22—The daily output of the Biggan Trailer Co. will reach 32 trailers within a few days, or equal to 4 carloads. At the present time approximately 50 men are employed in the plant, which number will be greatly increased as soon as more men can be obtained. The company is working on a government order for 500 trailers for the aviation department and expects to enlarge its plant shortly.

## Landing Field Chain Across Continent

Department of Military Aeronautics to Have Series of Fields 100 Miles Apart

WASHINGTON, Aug. 26—Construction of landing fields and training fields and enlargement of some of the existing fields have been ordered by the Department of Military Aeronautics. A chain of landing fields is being built across the continent at intervals of 100 miles. When they are completed they will be able to supply pilots, oil, gasoline, shelter, machine-shop facilities, maps, charts and barometer and thermometer ratings.

They are being built in New York, Pennsylvania, Ohio, Illinois, District of Columbia, Georgia, Texas, California, Arkansas, Mississippi, Alabama, New Mexico and Nebraska. The fields will no doubt enter largely into the location of future training fields, as they can be used for developing fliers, since they are sufficiently close to establish well defined air routes.

Bolling Field, District of Columbia, is to be improved by an expenditure of \$103,150. This field is being used for aerial patrol and protection of Washington as well as a training field for air service officers located in the capital. In addition to hangars and quarters sufficient for 23 officers and 154 enlisted men, there will be a balloon station with captive and free balloons for training observers. A photograph developing hut and a small radio telegraph station will also be features of this field.

The War Department now plans to train fliers in this country in squadrons to be shipped in such form to Europe instead of detachments as heretofore. Forty squadrons have been authorized. Four will be located at Houston, Texas, and thirty-six at Long Island, N. Y.

Major General William L. Kenly, Director of the Division of Military Aeronautics, states that this division is speeding up the training of fliers and is making ready to produce whatever number of fliers may be called for.

"Training schools," said General Kenly, "are now being grouped in districts so that the cadet fliers may pass from ground, primary, and advanced instruction all in one locality, and when the final test is passed be ready for France. It is also the intention as classes of these cadets finish their training as fliers to organize them into squadrons and brigades so that they may be sent overseas as such and take the air at the front in the formation in which they have been trained.

"Our study and observation and also the experience of officer instructors who have been overseas make us confident that this country offers the best training ground, not excepting England and France. This is primarily so because we have unlimited room here in the

United States. We are now equipping our flying fields with experienced instructors.

"In England and France the population is so great and uninhabited areas are so few and far between that it is difficult to locate even half a dozen training fields, to say nothing of several dozen. Over there, for instance, it is difficult to establish a gunnery school for fear of the damage that might be done to non-combatants or even to buildings. Gunnery schools require great areas of open ground in isolated districts. It is easy to locate such fields in the United States and at the same time have them accessible.

"The spirit of the West and the morale of officers and men, no matter whether they came from the North, East, South or West, is altogether splendid. They are absolutely fearless, show a high grade of intelligence and are bound to give a good account of themselves.

"One of the fields I visited was Mather Field at Sacramento, Cal. This field has a record of 250,000 hours of flying without a fatality. Another interesting place was the balloon field at Arcadia, Cal., where I saw seven balloons in the air at one time. The site of this field is a ranch back of which mountains rise to elevations the tops of which offer the same atmospheric conditions as the cadet gets suspended high in the air in the balloon basket. By taking the cadets up in these mountain tops, the instructors can train a large number at a time in observation and range-finding work, instead of limiting the classes to a few pairs in balloon baskets.

"We want good men in the Air Service, and we will need them in generous numbers. As soon as the new draft regulations are determined, I will venture to say that there will be unlimited opportunity for young men of the right calibre in flying schools and on the ground, for both this country and overseas."

### Naval "Hydro" Station for Morehead City

GREENSBORO, N. C., Aug. 26—The location of army activities in Charlotte, Wilmington, Raleigh and Fayetteville is to be followed by the establishment of a naval aviation station at Morehead City.

The Secretary of the Navy indirectly has confirmed reports that a hydro-aeroplane station is to go to Morehead City. It is understood that the naval training station is to be located at Camp Glenn, a site hitherto used by the National Guard of North Carolina as a rifle range and training camp.

### Oakland Employs Wives of Soldiers

PONTIAC, MICH., Aug. 26—The Oakland Motor Car Co. is giving the wives and sisters of employees who have gone into Government service preference in awarding factory positions. Women are employed in many departments, and the company reports they have proved themselves very efficient and versatile.

## Dope Making Plants Nearly Ready

Eight Chemical Units for Aircraft Bureau to Produce All Ingredients for Dope

WASHINGTON, Aug. 26—Eight chemical manufacturing plants, built for the Bureau of Aircraft Production, estimated to cost \$7,000,000, are now nearing completion. They will produce the necessary ingredients used in the manufacture of "dope" for coating airplane surfaces, immense quantities of which are used monthly, last month's supply alone running into 200,000 gal.

There are two principal types of "dope" now in use in the U. S. Air Service: cellulose nitrate "dope," used on training planes, and cellulose acetate "dope," used on all planes shipped overseas. Acetate "dope," when properly made and applied, is believed to give a better, more permanent and less inflammable coating than nitrate "dope." The characteristics of acetate "dope" are important in connection with the use on combat planes which are subjected to attacks with incendiary bullets.

Early in the preparation of the air program a standard "dope" was adopted and steps were taken to overcome the shortage of the ingredients and chemicals for the manufacture of cellulose acetate "dope." To-day, American plants, operating for the chemicals section of the Bureau of Aircraft Production, are turning out such materials as acetate of lime, methyl alcohol, acetone, glacial acetic acid and methyl ethyl ketone. From these materials "dope" is manufactured by several firms throughout the country for release through the chemicals section to plane manufacturers, aviation schools, fields and supply departments in this country and abroad.

The general method of doping the wing surfaces is to apply three or four coats of the "dope," intervals of several hours elapsing between the application of each coat. Because of the volatile nature of the thinners of solvents used to dissolve the "dope," the liquid portion evaporates quickly and the air in the vicinity becomes laden with the slightly injurious vapors of the solvents. On account of this evaporation the major portion of the solvents is lost, but steps have been taken to preserve the health of the workers and also to recover the solvent. Approved methods for recovery now make it possible to save from 50 to 85 per cent of the solvents lost during the process of doping and drying. Special "dope" containers are also provided which will reduce evaporation.

### Flags Fly on Milwaukee Plants

MILWAUKEE, Aug. 26—A service flag containing three gold stars, one silver star and 177 other stars was unfurled over the main office of the Wisconsin Motor Mfg. Co. at Milwaukee with impressive ceremonies on Aug. 23.

## Federal Approval for Road Building

### Beginning Next Month Road Material Cannot Be Delivered Without Formal Permission

WASHINGTON, Aug. 26—Federal approval will be required for all highway construction, according to the regulations made public to-day and effective next month, by the United States Highways Council, which governs highway and street work during the period of the war. Formation of this council was announced recently in these columns. It comprises representatives of the War Department, Agricultural Department, War Industries Board and Council of National Defense.

"No manufacturer," the council's announcement says, "will furnish any road-building material until the project has been approved by the United States Highways Council."

The proposed work that should be first submitted to the United States Highways Council through the appropriate State highway department is defined as follows:

"All proposed highway, street, culvert and bridge construction, reconstruction and maintenance involving: (a) the issuance of bonds; (b) the use of rail or water transportation; (c) the use of coal or oil as fuel; (d) the use of cement, brick, asphalt, oil, tar, crushed stone, or steel (also sand and gravel where shortage exists) as highway material."

The council urges that new highway and street construction be confined to most essential needs, and announces that it will give first consideration to the maintenance of highways already completed. Reconstruction is to be favorably considered only where it is clear that maintenance is no longer possible except at prohibitive cost.

New construction, it is announced, will be given consideration by the council in the following order:

First, highways and streets of military value, used regularly for the transportation of military supplies in considerable quantity, for the movement as an established practice of army-truck trains, or essential to the efficient operation of a military cantonment, post, or plant;

Second, highways and streets of national economic value, serving directly to promote the national welfare and not merely local welfare;

Third, unfinished contracts involving contractual obligations (incurred prior to April 5, 1918, where bond issue is involved) which may not be disturbed without serious consequences;

Fourth, streets and highways which although not of national economic importance are of extreme local importance, and the construction of which has progressed to such a point that serious hardship would be caused if their construction or completion should be postponed.

The council is soon to begin, in co-operation with the Bureau of Public Roads of the United States Department

of Agriculture, and the State highway departments, preparation of a program of road and street construction, reconstruction and maintenance throughout the United States for the working season of 1919.

The purpose is to approximate the character and amount of work deemed essential for 1919, with the amount and character of financing and materials involved, and the probable demand on rail and water transportation and labor supply. The preparation of the program in each State is to be in charge of the State highway department.

The United States Highways Council is composed of representatives from the Department of Agriculture, the War Department, the Railroad Administration, the War Industries Board, and the Fuel Administration. Logan Waller Page, director of the Bureau of Public Roads, is chairman of the council.

### Airplane Ambulance Successful

WASHINGTON, Aug. 26—Following the successful operation of the first ambulance plane at Gerstner Field, Lake Charles, La., General Kenly, commanding the Division of Military Aeronautics, has had all flying field commanding officers supplied with photographs and drawings of this new emergency air carrier, with orders to complete the equipment at once. The nine Texas fields have already finished their equipment.

The airplane ambulance is used in reaching scenes of accidents occurring at a distance from the flying field hospitals and in localities difficult to reach quickly with automobile ambulances. It is in turn followed by an automobile ambulance by road or overland as fast as is possible.

A standard training plane is used for the new airplane ambulance with the rear cockpit cleared and enlarged sufficiently to permit of a combination stretcher-seat that allows the injured man to rest easily. He is slightly propped up with his head toward the pilot and his feet and legs extending into the fuselage. The patient is securely strapped in and made quite as comfortable as in a regular ambulance. The real value of the plane is its speed, but it also assures a far more gentle and comfortable trip than is to be had in a rolling and bumpy automobile.

## Limit Coal Storage in East

### Fuel Administration Fixes Amounts Industrial Plants May Accumulate and Carry

WASHINGTON, Aug. 26—The tremendously increasing demand for coal for special war purposes in the eastern part of the country, particularly for the Navy and Transport Service, is making it necessary to draw more heavily on the Eastern coal fields than was originally contemplated.

It has therefore been decided to limit the amount of coal storage that industrial plants would be allowed to accumulate and to carry on hand and to fix a uniform amount that each State may accumulate.

United States Fuel Administrator Garfield announced the basic policy of the Fuel Administration as to storage as follows:

### April, 1919, Deliveries for Excess Coal

"Coal in excess of that required for current operations shall be delivered to plants not on the preference list of the War Industries Board only when it is not in demand for use before April 1, 1919, by consumers on said list, namely, railroads, the Federal Government, states, counties, public utilities, retail dealers, or manufacturing plants on the Preference List.

"In carrying out this policy, allowance shall be made for differences in distance from the mines and for differences in transportation conditions which may require more or less storage at the beginning of winter to insure uninterrupted operation until the following spring."

The following report, framed by a committee of State Fuel Administrators aided by officials of the Administration, was adopted by the conference and concurred in by Dr. Garfield:

"The maximum limits of storage indicated for the several States or parts of States defined hereafter are as follows:

### Maximum Number of Days Storage Bituminous Coal Allowed Until Further Notice

	Steam Coal		By-Product and Gas Coal

### Hare Made Packard Vice-President

DETROIT, Aug. 26—Emlen S. Hare has been elected to a vice-presidency of the Packard Motor Car Co., Detroit. He will retain his position as president of the Packard branch in New York, but will remove to Detroit within a few weeks. The rapid development of the Packard company's work for the Government has absorbed President Alvan Macauley's time and energies to an extent that warranted the creation of the new office for which Mr. Hare has been chosen. He joined the Packard forces early in 1916 in the capacity of special sales representative of both the New York and Philadelphia branches. Within 6 months he was given supervision of the truck department of the Packard Motor Co. of New York. A month later he was promoted to general manager, and later was made president.

J. J. Wright, for 2 years manager of the Ford branch at Memphis, has been promoted to manager of the branch at St. Louis, where new offices will be opened, the assembly plant there having been turned over to the United States. Wright succeeds W. C. Anderson, made manager of the assembly plant at Chicago. C. S. Williams, of the Louisville branch, becomes manager at Memphis.

Glen A. Sanford has been appointed sales manager of the rim division of the Jaxon Steel Products Co., Jackson, Mich.

B. A. Guy, secretary and assistant general manager of the Curtiss Aeroplane & Motors Corp., Buffalo, resigned Aug. 15.

R. T. Hodgkins has been appointed general sales manager of the Cleveland Tractor Co., Cleveland. For the past 4 years he was general sales manager of the Studebaker Corp., and previous to that was connected with the Yale & Towne Mfg. Co., New York.

L. S. Nold, formerly of the Electric Vehicle Co., also the General Electric Co., on Aug. 23 became identified with the Mitchell Motors Co. as secretary and treasurer. W. H. Armstrong, for 8 years secretary and treasurer of the Mitchell company, resigned to devote his time to other interests in Racine.

Bert B. Fornaciari, secretary and general manager of the Harvey Motor Truck Co., Harvey, Ill., for 9 years, has been appointed production manager and chief engineer of the Midland Motor Car & Truck Co., Oklahoma City. W. B. Burgess, in charge of the cost, time and stores departments of the Harvey company for 2½ years, and assistant to Fornaciari at Harvey, has also joined the Midland forces as assistant production manager.

C. B. Meyers has been appointed manager of the sales promotion department of the United States Motor Truck Co., Cincinnati. He has been with the company for 6 years, starting as stenographer

## Men of the Industry

### *Changes in Personnel and Position*

#### Squires Will Leave Signal

DETROIT, Aug. 23—John Squires, chief engineer of the Signal Motor Truck Co., has handed in his resignation to the company to become effective Sept. 1 and will go into business for himself. S. Deutsch, vice-president of the company, will take up his duties when the position becomes vacated.

#### Hood Forms Garage Company

DETROIT, Aug. 26—Wallace C. Hood, who recently resigned as sales manager for the King Motor Car Co., Detroit, has formed the Foster-Hood Sales & Service Co. Mr. Foster was also formerly connected with the King company in the capacity of service manager. The Foster-King company will do general garage work, automobile painting, top recovering, etc., at 418 Jos. Campau Avenue.

and filling subsequently the positions of purchasing agent and sales manager from the time of its reorganization.

Charles M. Wallace, formerly purchasing agent of the Buda Motor Co., Harvey, Ill., and later with the Mitchell Motors Co., has been appointed manager of the purchasing department of the Erd Motor Co., Saginaw, Mich.

#### Ordnance Board on Metallurgical Matters

WASHINGTON, Aug. 26—In order to assure the more complete co-ordination of the various ordnance departmental activities along metallurgical lines, it has been decided to establish a Board on Metallurgical Matters. The appointment of this board will also assure the complete co-ordination of similar activities of the different divisions of the War Department and the War Industries Board.

The personnel of the board is as follows: Dr. G. W. Sargent, Engineering Division, chairman; Lieut.-Col. W. P. Barba, Production Division; Major A. E. White, Inspection Division, representing the Ordnance Department; Lieut.-Col. F. B. Richards, of the office of the Assistant Secretary of War; L. L. Summers, representing the War Industries Board, and William H. Smith, representing the manufacturers.

The board will act not only for the various sections of the Ordnance Department, but also in connection with the manufacturers working for and with the department in the production of war material, and will gather the most recent and complete information on all metallurgical products.

#### Swope Appointed Assistant to Baruch

WASHINGTON, Aug. 22—Herbert Bayard Swope has been appointed by the War Industries Board as an associate member. He will act as assistant to Chairman Bernard M. Baruch. Mr. Swope is a well-known editor who has studied war problems both in this country and abroad.

L. W. Hamilton has been elected president and general manager of the Lane Motor Truck Co., Kalamazoo, Mich., succeeding Dr. W. W. Lang, who has resigned. E. W. Bitzler has been appointed secretary and treasurer.

H. B. Garman has been appointed manager of the Detroit plant of the Steel Products Co. He was formerly superintendent of the plant, in which are manufactured drag links, brake and truss rods, propeller tubes, etc.

W. F. Winkleman has resigned as special representative for the Liberty Motor Car Co., Detroit, and is now associated with the Heath-Duplex department of the McCord Mfg. Co., Inc. He has been identified with the automobile industry for the past 12 years.

W. H. Yule, head of the mechanical goods department of the B. F. Goodrich Rubber Co., Akron, has been placed in direct charge of the company's relations with the Government. He has been in charge of mechanical goods sales for 2½ years, rising to that position from the managership of the Goodrich branch at New York City.

P. R. Preston, advertising manager, Rock Island Plow Co., Rock Island, Ill., has resigned and gone into the service with a machine gun company.

George V. McMahan, who was sales manager of the Detroit branch of the Remy Electric Co., has been promoted to assistant general manager of the Remy Electric factory at Anderson, Ind.

Alexander Dow, an inventor and a prominent witness in the Perlman rim case, has been commissioned a captain in the ordnance department. He is at present stationed at the Western Cartridge Co., East Alton, Ill.

#### Eagle No. 2 Launched at Rouge

DETROIT, Aug. 26—Eagle No. 1 is rapidly nearing completion at the Ford shipbuilding plant and will be ready to start shortly. Every piece of machinery, bolt and nut or piece of pipe used has been carefully measured and standardized, so that for all future boats everything will be ready to fit in place before launching. Eagle No. 2 was launched last Tuesday; Eagle No. 3 will leave the ways early this week, after which the chasers will go almost at the rate of one a day.

**Janesville Starts New Plant**

JANESVILLE, WIS., Aug. 26—The Janesville Machine Co., Janesville, Wis., recently acquired by the General Motors Corp., as the nucleus of a new tractor and implement manufacturing industry, has broken ground for the first unit of its proposed new tractor plant in Janesville. The main building will be 214 x 540, with a wing 50 x 250, and arranged for machining, assembling and erecting farm tractors. Later a complete foundry unit will be added. It is hoped to have the first unit ready by Nov. 1. In the meantime the original plant of the Janesville Machine Co. will be enlarged and changes made to make the production one of farm implements and tools suitable for tractor combinations. The initial investment in the new tractor plant will be approximately \$250,000. The Sampson sieve grip will be manufactured exclusively.

**60 Per Cent General Motors Capacity War Work**

DETROIT, Aug. 26—The General Motors Corp. is already on about a 60 per cent war work basis, and by winter it is believed 75 per cent of the capacity of all G. M. C. plants will be on a war basis. The Oldsmobile, Oakland, Chevrolet and Buick will all be truck producers, in addition to the G. M. C. Truck Co., Pontiac. The passenger car makers will produce  $\frac{1}{2}$  to 1-ton models, while the G. M. C. Truck Co. has models of  $\frac{1}{2}$  to 5 tons.

**Brisk Blast Co. Reorganizes**

MONROE, MICH., Aug. 23—The Brisk Blast Co., formerly of St. Louis, Mo., now located in Monroe, was recently reorganized, J. L. Phelps of St. Louis having disposed of his interests in the company. New officers of the company are: President, C. B. Southworth; vice-president and treasurer, Charles McIntyre; secretary, J. F. Meyer. This concern manufactures automobile accessories and airplane parts.

**Remy to Have New Administration Building**

ANDERSON, IND., Aug. 24—A new administration building is being erected by the Remy Electric Co. The general offices of the company have been moved into temporary quarters until the new building, which will occupy the ground where the old Remy administration building stood, is completed.

**Hartford Plant for International Steel**

MILWAUKEE, Aug. 26—The International Steel Products Co. has selected Hartford, Wis., as the location of its new plant, which will be devoted largely to the manufacture of the "Uvee" muffler. The concern has purchased a site of  $3\frac{1}{2}$  acres near the plant of the Kissel Motor Car Co. at Hartford and will start building operations this week. Hartford capi-

## Current News of Factories

*Notes of New Plants—Old  
Ones Enlarged*

tal has taken a large financial interest and will be the controlling factor in the new works.

**More Room for Schacht**

CINCINNATI, Aug. 24—The Schacht Motor Truck Co. has begun the erection of an addition to its plant which will increase its capacity to 3000 trucks a year. It now turns out about 1200. The enlarged plant will employ about 800 men, and will cost about \$300,000. The new plant will be completed by the first of the year.

**More Tractors From Peoria**

PEORIA, Aug. 26—The Wilson Tractor Co. has been organized here and will have temporary headquarters at 213 South Water Street. The promoters will shortly open a factory to manufacture farm tractors. Articles of incorporation have been secured, the capital stock being fixed at \$5,000. The incorporators include J. B. Barrett, D. O. Wilson and M. E. Dryden. In the near future a factory site will be purchased and a building of large size erected.

**Maxwell Production Down**

DETROIT, Aug. 23—The Maxwell Motor Co., which has gone into war work on a large scale jointly with the Chalmers, has cut its production of passenger cars sharply. For the 6 months ended June 30 its output was about 50 per cent of the total of a year ago, or 22,000 cars, as against 43,500. Its truck production decreased from 12,000 to 4000.

**13,979 Cars a Week on Akron-Cleveland Road**

AKRON, Aug. 26—A striking illustration of the use of the highways by motor vehicles was presented by a census for a week taken in March of vehicles traveling over the 40-mile stretch of Ohio roads between Cleveland and Akron. The registration gave a total of 13,979 vehicles, of which only 685 were horse-drawn. Fifteen per cent of the total were motor trucks, which carried 5014 tons of freight, as compared to 6630 tons shipped by three railroads. Thirty-three thousand people were transported in passenger automobiles.

**Packard Declares Dividend**

The Packard Motor Car Co. has declared a regular quarterly dividend of  $1\frac{1}{4}$  per cent on the preferred capital stock, payable Sept. 16 to stockholders of record Aug. 30.

**Doehler Enlarges Plant**

TOLEDO, Aug. 26—The Doehler Die Castings Co. has begun the erection of two new buildings, to cost \$100,000, which will be used principally for the manufacture of airplane bearings and other war products. One building, which will be an addition to the machine-shop, is to be 160 by 50, four stories high. The other, 50 by 120, will be a new foundry building. It is expected that the new buildings will be completed within 3 or 4 months. To obtain increased production, 500 employees will be taken on in addition to the 800 or 900 at present working in the plant.

A new department also will be started with the completion of the new machine-shop. Heretofore all aluminum die castings have been made in the Brooklyn plant. A large number of machines will be installed and the castings will be manufactured here.

The Dohler company has large Government contracts for war materials, including shells, depth bomb fuses and airplane parts, and recent contracts call for approximately 90 per cent of the airplane bearings used by the Government in all types of machines. Besides furnishing bearings for the new airplanes, the Doehler company already has made more than 500,000 bearings for United States aero training stations.

**Reo Awarded Tractor Order**

LANSING, Aug. 26—The Reo Motor Car Co. has been awarded an additional Government contract for artillery tractors, the quantity of which or the proposed date of delivery is held confidential. It is known, however, that the work on the second contract, supplementing the first award of 3000 tractors, will keep the Reo plant working to capacity for nearly a year.

The Reo company will continue to manufacture trucks until such time as steel needs conflict in any way with Government war needs. There are certain departments where the production of trucks will not interfere with tractor production, for the time being at least. The truck plant, which previous to the additional tractor contracts, had been converted into strictly a tractor production plant, is now shipping carloads of tractors daily on the original contract. Four milling machines are to be installed in this plant for work on tractor frames, each of which handles two tractor frames at a time. A 12-hour schedule is being maintained, with over-time work when necessary. To facilitate Government work the Reo baseball league has abandoned its schedule and there are no more Saturday half holidays.

**Overland to Make Liberty Engines**

ELYRIA, OHIO, Aug. 26—The Willys-Overland plant in this city has announced it will begin the manufacture of eight and twelve-cylinder Liberty engines. The plant will operate 24 hr. a day, giving employment to more than 2000 men.

# Industrial Review of the Week

## A Summary of Major Developments in Other Fields

### Production of Bituminous Continues to Decrease

Production of bituminous coal continues to decrease in spite of all efforts made by operators and Fuel Administration officials to speed up production. The causes for the poor output still remain the chronic ones of insufficient cars and slacker labor. Many of the producing districts report that their operations have been forced to suspend for periods ranging from half a day to four days because they were given no cars to load. Not only does this poor transportation situation result in meager tonnages, but patriotic labor that is anxious to prove its good intentions toward the country at the present time is denied the opportunity to work steadily.

During the week ended Aug. 17 inadequate car supply and labor shortage combined to keep the output of soft coal down to 11,910,000 net tons, which is far below the weekly figure of 14,270,000 net tons considered necessary to meet essential demands. It is a foregone conclusion that some drastic policy will have to be put into effect if war work is not to suffer, and an intimation of the manner in which the situation will be met is indicated by the announcement of the Fuel Administration that stocks of steam, by-product and gas coals are not to be hoarded, regardless of whether the consumer with the reserve stores is in a preferred or non-preferred industry. Mandatory limits have been set on the number of days' supply of fuel which may be stored by industries in different sections of the country, and the Fuel Administration will see to it that these limits are not exceeded.

The movement of coal to the Northwest shows signs of improvement, though the tonnage is still considerably behind pre-season estimate. Bituminous coal loaded on vessels at lake docks during the week ended Aug. 17 amounted to 1,109,611 net tons, an increase over the week preceding of 85,192 net tons. Supreme efforts will be required if the Northwest's requirements are to be met before the close of the lake season.—*Coal Age*.

### Aircraft Report Unfair to Industry (Continued from page 377)

which the committee gets away from the European parallel and apparently forgets entirely that the aircraft development in England, France, Italy and Germany was carried on entirely by the automobile industry, and that it was the logical industry, and the only one well fitted to take up the work. We cannot see where any other industry could have been found so well qualified to do the work in America.

The report seems in many places to be based on the complaints of some aircraft manufacturers that were in existence

previous to the war, but who had no conception of or facilities for production manufacture. Those from the automobile industry who entered into the aircraft program have been criticized on the grounds of favoring the industry, which criticism has been unjust. It would be impossible to find manufacturers better qualified to carry on the work than those who had been given the task.

It is true that the orders might have been spread over more companies, as has been done in England. This, of course, would have worked against production, and undoubtedly those in charge of the program had in mind concentrating production in a few large companies in order to meet the requirements.

The question of manufacturing tools and jigs for production, and the enormous difficulties involved, has not been given due consideration in the report. The spirit of the report seems to be a general condemnation of the aircraft activity to date, and after reading the evidence of many who were heard by the committee you cannot but conclude that the report is unfair to the industry. It has not given that prominence to much of the evidence that should have been brought out in the report. It savors too much of nailing the complete responsibility on an industry and whitewashing the Government side of the question. It is not fair to censure one and overlook the other.

The report will have one value, if its general circulation in America is permitted, namely, that of educating the public to a great extent on aircraft. Practically every person examined in connection with it admitted the greatness of the task and the inexperience of the nation.

This report should serve as a great educator. It is true it tells some unpleasant things, some that will have a depressing effect throughout the country; but we are in war, and must lay our cards on the table. If we have to go through the fire and water, let us do so now, and get on firm ground, so that we can correct those abuses of government and industry which have taken place in the last 16 months.

### General Motors Increases Stock

WILMINGTON, DEL., Aug. 27—At a special meeting of the stockholders of the General Motors Corp it was voted to increase the capital stock from \$200,000,000 to \$300,000,000. The preferred stock was increased from \$50,000,000 to \$100,000,000, and the common from \$150,000,000 to \$200,000,000. A bonus plan providing for the distribution of 10 per cent of the net earnings each year to the employees of subsidiary companies as a reward for their part in the success of the respective subsidiaries was also approved.

### 23,000,000 Tons of Steel Needed Before End of Year

With more emphasis than ever the War Industries Board has put before the steel trade in the past week the imperative call for rails, plates and shell steel. New needs cabled from France have added to the gap between capacity and requirements, and the amount now wanted in the last four months of the year will bring the total for the second half up to 23,000,000 tons, as against an estimate of 20,000,000 tons early in July and probable production of 17 to 18 millions for the six months.

Yet output does not increase, and every nerve must be strained to make up in September for the inroad made by an unusual number of hot and highly humid days in August.

A swelling of overseas demand, due to the aggressive activities of the Allied forces, has changed greatly the operating schedules of the mills. Urgent calls have been received for rails, rolling stock and shell steel, and, temporarily, some home needs, even cars for our own roads, may have to stand aside.

The details of the \$5 a ton concession on implement steel are being arranged. The cold-rolled shafting schedule was arranged in a New York meeting last week.

Last year's heavy accumulations of export steel at Atlantic ports waiting for ship room were cut down 700,000 tons in the first seven months of this year. Mills have been urged to build up stocks for France at seaboard against the railroad blockades of winter, but thus far have fallen steadily behind the ocean movement.—*Iron Age*.

### Coffin Protests to Congress

(Continued from page 360)

eration to the contents of my letter of Aug. 14, to the end that both the Senate and the press may be informed as to the correct status of the three organizations involved in the governmental aircraft program, namely, the War and Navy departments and the non-executive, advisory Aircraft Board.

Much misunderstanding of the situation has arisen because of the dual functions of the officer members of the Aircraft Board, namely, advisory and non-executive when sitting with the board, but executive when functioning as the heads of Army and Navy bureaus. All technical and executive work as to selection of types of machines and their production has by law and by necessity rested until within the jurisdiction of the governmental departments, upon which the civilian members of the board have been dependent for all information and for all contact with military and naval air service progress.—H. E. COFFIN.

## Aircraft Contracts Placed

WASHINGTON, Aug. 26—Following is a list of contracts made by the Bureau of Aircraft Production:

August 12, 1918

1867-D. Wright-Martin Aircraft Corporation, New Brunswick, 2000 Hispano Sulza 300-hp. engines.

Curtiss Aeroplane & Motor Corp., Buffalo, plain hexagon head bolts with castellated nuts.

Curtiss Aeroplane & Motor Corp., Buffalo, machine bolts and castellated nuts.

Armstrong Bros. Tool Co., Chicago, Ill., 2400 structural wrenches, 100 C clamps. Hoosier Veneer Co., Indianapolis, 17,000 ft. walnut lumber.

Pickrel Walnut & Veneer Co., St. Louis, Mo., 40,000 ft. walnut lumber.

George W. Hartzell, Piqua, Ohio, 95,000 ft. walnut lumber.

Des Moines Sawmill Co., Des Moines, Iowa, 500,000 ft. walnut lumber.

Howell & Lesser, San Francisco, Cal., spares for 75 JN4D planes, elevators, landing gears, rudders, wings, etc.

Curtiss Aeroplane & Motor Corp., Buffalo, sets dual controls for 436 JN6H advanced training planes.

Curtiss Aeroplane & Motor Corp., Buffalo, 91 sets dual controls for JN4D planes.

F. A. Requarth Co., Dayton, 75 gear training models.

United States Aircraft Corp., Redwood City, Cal., spares for 50 JN4D planes, elevators, vertical fins or stabilizers, landing gears, rudders, wings, etc.

Curtiss Aeroplane & Motor Corp., Buffalo, 26 sets upper wings, with ailerons.

General Motors Corp., Flint, 5000 Liberty 8-cylinder motors.

Packard Motor Car Co., Detroit, 100 Liberty 12-cylinder aviation engines.

4465. Norwich Chemical Co., Smethport, Pa., 4500 gal. acetone.

W. S. Gray & Co., New York City, 5000 gal. methyl ethyl ketone.

American Cyanamid Co., New York City, 2350 lb. urea in containers.

### Goodyear Claims Its Policies Not Understood

AKRON, Aug. 23—The Goodyear Tire & Rubber Co. in commenting on the charges made against it by the Federal Trade Commission claims that it has not required dealers to sell Goodyear products exclusively nor has it asked them to confine their services to Goodyear tires exclusively. The company has merely pointed out the necessity, from the consumer's standpoint, for this service, and has insisted that dealers upon signing the company's contract undertake to render the agreed service. The company further claims that it has made no effort to curtail, control or restrict the operations of

## Contracts

dealers, simply insisting that the consumer must be served.

The complaint of the Federal Trade Commission is based on a preliminary investigation. As yet the Goodyear company is not aware of the nature of the investigation and has not had an opportunity to explain the facts in the case. When this opportunity is presented, the company feels confident that all the items in the charge will be cleared up.

To the company the whole problem gets back to the sincerity of its service station plan and the motive underlying it. The company believes that if the Federal Trade Commission now knew that the whole aim and effect of the company's policy is to aid tire users to conserve tires, get more mileage and hence cut down tire expense, this complaint would not have been made.

Claiming to have based all its policies on thorough investigation, careful analysis and expert legal advice, the company believes that when the facts are known to the Federal Trade Commission the complaint will be dismissed.

### 270 Airplane Mail Trips

WASHINGTON, Aug. 24—From May 15, when the Air Mail Service was inaugurated, to Aug. 12, when the military authorities turned over the service to the Post Office Department, a total of 20½ tons of mail was dispatched between New York and Washington. This included 270 flights covering 421½ hr. of flying, with a total of only sixteen forced landings. This information was made public to-day in a letter by Postmaster General Burleson to Secretary of War Newton D. Baker, advising him of the completion of the transfer of the equipment and the flying operations of the Aerial Mail Service from the War Department to the Post Office Department.

### A Navy Department Contract Placed

WASHINGTON, Aug. 24—The Bureau of Supplies and Accounts of the Navy Department has placed the following contract:

Cadillac Motor Car Co., Detroit, Mich., spare parts.

### Two Contracts Are Placed by the Army

WASHINGTON, Aug. 24—The Quartermaster General of the Army has placed the following contracts:

Ford Motor Co., Detroit, Mich., spare parts for cars.

The Goodyear Tire & Rubber Co., Akron, Ohio, tires.

### Moline Tractor Notes

NEW YORK, Aug. 22—The Moline Plow Co., Moline, Ill., manufacturer of the Moline farm tractor as well as Moline farm machinery, has placed an issue of \$6,000,000 serial notes on the market, the money being used to fund bank loans which have been incurred to take care of the increased manufacturing activities, stock, raw materials and general expansion of the company.

The notes will bear date of Sept. 1, 1918, and will fall due in six installments beginning with Sept. 1, 1919, and running until Sept. 1, 1924. The notes will yield 7½ to 7% per cent interest.

The present capitalization of the company is as follows:

First 7% preferred stock..\$7,500,000  
Second 6% preferred stock. 1,500,000  
Common stock .....10,000,000

The company's sales for the 11 months ending July 31, 1918, were \$17,315,036, as compared with \$13,140,450 for the preceding 12 months.

### Firestone Sales to Touch \$75,000,000

AKRON, Aug. 26—The Firestone Tire & Rubber Co. estimates its sales will approximate \$75,000,000 for the fiscal year, allowing for the restrictions on the importation of crude rubber and the production of pneumatic tires. The company is devoting its plant to rubberized fabric, balloons and gas masks.

# Calendar

## ENGINEERING

Sept. 2—Cripple Creek, Colo. American Institute of Mining Engineers.  
Nov. 14-15—New York. Society of Naval Architects and Marine Engineers. Twenty-sixth general meeting. Engineering Societies Bldg., 29 West 39th Street.

## ASSOCIATIONS

Oct. 7-12—Milwaukee. American Foundrymen's Assn. and 5 allied organizations. Milwaukee Auditorium.

## SHOWS

Aug. 29—Laconia, N. H. Tractor demonstration County Farm Bureaus). M. C. Wilson, Director, Agricul-

ture Extension, Dunham, N. H.

Aug. 28-30—West Raleigh, N. C. Tractor demonstration (Farmers' Convention, College Farm). Dr. R. Y. Winters in charge.

Aug. 30—Campton, N. H. Tractor demonstration (Albion Farms). H. G. Gulliver, Mgr.

Aug. 30—Cheshire, Conn. Tractor demonstration (New Haven County Farm). Mr. Harvey, Mgr.

Aug. 30-Sept. 8—Detroit, Mich. Automobile exhibits, State Fair.

Sept. 2-6 — Hartford, Conn. Tractor demonstration (State Fair). Will F. Landon, Secy.

Sept. 2-7—Indianapolis, Indiana.

State Fair. Indianapolis Automobile Trade Assn.

Sept. 5—Medina, Orleans Co. Tractor demonstration (State Fair) Food Commission. Calvin J. Huson, Director.

Sept. 8-20—Greely, Weld Co., Colo. Tractor Show, Central Community Fair.

Sept. 9-14—Milwaukee. Milwaukee Automobile Dealers, Inc. Fourth Annual Wisconsin State Fair. Hart J. Ruddle, Mgr.

Sept. 9-14 — Syracuse, N. Y. Tractor demonstration (State Fair). J. Dan Ackerman, Secy.

Sept. 12-13—Marion, O. Tractor demonstrations, Farm Bureau Associations. M. C. Thomas, County Agricultural Agent.

Sept. 17-20—Riverhead, L. I. Tractor demonstration (County Fair). Harry Lee, Sec'y.

Sept. 30-Oct. 4—Trenton, N. J. Tractor demonstration (Trenton Fair). Harry B. Salter, Supt.

Oct. 30-Nov. 4—Shreveport, La. Tractor demonstration, State Fair.

Nov. 11-16—Phoenix, Ariz. Tractor demonstration, State Fair.

## RACING

Sept. 2—Uniontown. Uniontown Speedway Assn.

Sept. 7 — Chicago. Chicago Speedway.

Sept. 21—Sheepshead Bay.

Oct. 5 — Cincinnati. Cincinnati Speedway.

# Complete Text of Senate Aircraft Report

## REPORT RECOMMENDS

- |   |  |
|---|--|
| 1—One-man control of aircraft activities.             | 5—Encouragement of invention in aircraft activities. |
| 2—Commission of engineers to go to France.            | 6—More protection for aircraft patents.              |
| 3—Wider distribution of engine and plane manufacture. | 7—Cost of construction defects be carried by maker.  |
| 4—Great expansion of our air policy.                  | 8—Better fire protection at factories.               |

## REASONS FOR FAILURE ARE

- |  |  |
|--|--|
| 1—Ignorance of aeronautical problems by automobile industry. | dominated work entirely too much.                                    |
| 2—Standardized engine program has                            | 3—Should have more quickly taken up manufacture of European designs. |

## MISCELLANEOUS

Criticises severely the patent cross-licensing scheme.

Gives reason for failure of Bristol plane.

Complete information on our flying fields:

Manufacturers' difficulties with tool and jig production not given enough prominence.

Complete information on our plane program, including De Haviland 4, Handley-Page, Caproni, Bristol and other types.

European aircraft engines that we are now manufacturing.

Over 100 different witnesses examined for evidence.

The following is the text of the report of the sub-committee on Military Affairs, which was appointed to investigate aircraft invention in the United States:

### Summary

On April 6, 1917, the United States entered the war.

On June 8, 1917, public announcement was made that a great fleet of 25,000 aeroplanes was about to be created, and would be decisive of the war months before an effective army could be put in Europe.

July 24, 1917, Congress appropriated \$640,000,000 to carry out the aircraft program. This fund has been, either by

actual expenditure or by commitments, exhausted. A further appropriation of \$884,304,758 has been found necessary.

In the opinion of the committee a substantial part of the first appropriation was practically wasted.

While much good work has been accomplished, for which due credit should be given, it must nevertheless be admitted that our aeroplane program has, up to the present, presented many aspects of failure. To some of these we call attention:

While an army of three and one-half million has been raised, the aircraft situation is as follows:

a—Six hundred and one De Haviland

4's have been embarked for France up to Aug. 1, 1918.

Of these, sixty-seven had reached the front by July 1.

On Aug. 7 a squadron of eighteen De Haviland 4's flew over the German lines. Details of its performance have not been received. The character and construction of the De Haviland 4 is further discussed in paragraph i and in the body of this report.

b—We have not a single American-made Chasse (or plane of attack) upon the battle front.

c—We have not a single American-made heavy bombing plane upon the battle front.

d—We have not developed and put in quantity production a successful Chasse, or fighting plane.

e—Our attempt to create a fighting plane was centered in an attempt to adapt the Bristol Fighter and the De Haviland to the Liberty motor. The Bristol was, without sufficient tests, put in quantity production, over \$6,500,000 expended, and the lives of several gallant men sacrificed, when the machine was condemned and its manufacture discontinued.

f—The Standard J training machine was equipped with the Hall-Scott engine and put in quantity production. After more than 1200 had been manufactured at a cost of \$6,000,000 the machine thus equipped was condemned as dangerous and placed in storage.

g—The Spad is a Chasse or fighting plane of the highest type. Early in September an oral order was given to the Curtiss Aircraft Co. for the manufacture of 3000 of these machines. Work was at once begun and drawings practically completed.

On Sept. 27, Colonel Clark and Major Vincent (one of the inventors of the Liberty motor) concluded that the machine could not be operated with a Liberty motor.

On Oct. 8 the contract was canceled, the reason given being that the single-seat fighter was regarded as obsolete. But the fact is that on April 23, 1918, a contract was let to the Curtiss company to build 1000 single-seat fighters, known as the S. E. 5, which is the English equivalent of the French Spad.

In addition to this, our Government is now using upon the battle front every Spad machine it can secure from the French, but has only been able to obtain about 418 of them.

i—The cancellation of the Spad contract and the failure of the Bristol left us without either a single or a two-seat fighter, except the De Haviland 4, which was originally designed as a two-seat fighter and which we are equipping for reconnaissance, photographic, bombing and fighting purposes.

Contracts for 8500 were let at various times. Up to Aug. 1, 1000 had been delivered, and a number forwarded to General Pershing. An inspection and test developed numerous mistakes, both in design and workmanship. Work upon the planes was stopped until the defects could be remedied. In part this appears to have been accomplished in the field, for a squadron of eighteen planes has been sent across the German lines.

k—As early as the month of October, 1917, we were in possession of the necessary facilities to construct the Caproni, a powerful and successful heavy bombing plane, approved both by Italian and English aeronautical engineers.

Expert Italian engineers have been upon the ground since the month of January, yet the fact remains that we have up to date constructed only one experimental machine which is equipped with Liberty motors.

Nearly a year has elapsed since we might have begun work upon these ma-

chines and by this time have been in quantity production.

l—The Handley-Page heavy bombing machine furnishes another example of delay. Plans were furnished the Signal Corps in the summer of 1917, but were not then availed of. Contracts for spare parts were not made until February, 1918. Deliveries of these spare parts did not begin until August, 1918. A sample plane ordered in March, 1918, was flown last July. Tests are not yet complete.

#### Causes of Failure

In the opinion of the committee the disappointing results above set forth are chiefly due to three causes:

I. That the airplane program was largely placed in the control of the great automobile and other manufacturers, who were ignorant of aeronautical problems.

II. These manufacturers undertook the impossible task of creating a motor which could be adapted to all classes of flying craft. It is not too much to say that our airplane program has been largely subordinate to the Liberty motor.

III. We failed at the beginning of the war to adopt the common-sense course of reproducing the most approved types of European machines in as great numbers as possible. This should have been carried on coincident with the production of the Liberty motor. This sound policy has very recently, but after a lamentable lapse of time, been adopted.

#### One-Man Control

The mistakes and errors referred to would probably have been largely avoided if the aircraft program had been under the control of one man, assisted by skilled aeronautical engineers and practical flyers to design and test our machines, with production made subordinate to them.

This brief summary is not a wholesale condemnation of our aircraft program. Much has been accomplished. The committee is glad to report that while it believes there are yet many things to be remedied, nevertheless we are approaching a period when quantity production of planes may soon be hoped for.

#### The Aircraft Board

As originally composed, representatives of the automobile industry featured this organization, presumably due to the theory that aircraft engine and plane production were analogous pursuits. The latter was therefore submitted to the custody of men skilled in automobile production. A board thus equipped naturally depended upon motor-car engineers and manufacturers for the solution of aviation problems. But the analogy between the two pursuits virtually begins and ends with the fact that each uses a gas-explosive motor. Hence difficulties in design and production would tend to increase until such conditions were recognized. This fact must have been demonstrated to the board through its initial experiences, for Major Downey states that in the beginning the board wanted much authority with little responsibility.

"They wanted the Signal Corps to

execute contracts and stand back of them, the board to be in an advisory capacity, and still control the situation."

Later, when—

"They saw the crash coming the board passed a resolution reaffirming the fact that they were only acting in an advisory capacity."

Organization under the Aircraft Board was unsystematic and ineffective. The chief officer of the Signal Corps was the nominal head, under whose ostensible supervision bureaus of engineering, equipment, supplies, lubrication, production, etc., were established, many of whose functions ill defined, conflicted with or overlapped each other. Contractors, inventors, material men, everyone having business with this part of the service and directed from one official to the other could not well transact their business and secure results with directness and efficiency. While this condition seems to be inseparable from official business routine in Washington, it featured largely in aviation from the start, materially hindering production on the one hand and diffusing responsibility therefor upon the other. Fairness, however, requires the statement that the identification by Congress of aircraft production and administration with the Signal Corps was unfortunate. The primary needs and importance of that corps as then defined were fully equal to the experience and efficiency of its commanding officer.

#### How Italy Started

When Italy entered the war she made a careful study of aerial warfare upon the French front as then developed. Her engineers then selected the most efficient types of French flying planes and immediately put them into production under the supervision of skilled French artificers. Coincident with this policy she began the development of airplanes on her own account. Her armies were, therefore, rapidly equipped with an excellent service, afterward supplemented by machines equally effective, but of Italian design and driven by Italian motors. By this means she avoided delay in production. She also promoted the development of her engineering genius by employing it under practical conditions upon the front with the best machines that France had produced.

#### The Bolling Mission

Your committee does not understand why the Aircraft Board did not adopt this obviously essential policy. The Signal Corps dispatched a commission to the front, headed by Colonel Bolling, instructed to secure all needed information, evidently for that purpose. Col. E. V. Clarke, the aeronautical engineer of the commission, made an elaborate report, having Colonel Bolling's approval, recommending the production of three English, two French and one Italian plane, but the report was not heeded. Designs for these and other types were placed by the allied Governments, or by the inventors themselves, at the board's disposal, with assurances of expert aid to their vigorous construction.

An ostensible reason assigned for the board's inaction was the difficulty of translating metrical into linear measurements, and of obtaining quantity production of foreign motors. But the tardy acceptance and manufacture of some of the models and designs revealed the imaginary character of this objection. The board took some of the planes placed at its disposal and attempted with ill success to materially change them for American production. The general purpose of the changes seems to have been designed to adapt them to the Liberty motor, but this normal action should have been paralleled by their manufacture, both as to plane and engine, in strict accord with the plans as submitted.

#### Planes for Liberty Engine

Ultimately, and in the autumn of 1917, the board adopted one French and two English types of fighting planes to carry the Liberty engine. These were the Spad, the Bristol and the De Havilland 4. Colonel Clarke was instructed to redesign the Bristol upon the English model, retaining its wing load of about 7.1 lb. in a total weight of 2937 lb.

Hundreds of changes afterward made in this design by Signal Corps and production engineers without consulting Colonel Clarke increased the wing load to about 9.2 lb. per foot, with an approximate weight of 3700 lb. Some of these changes were required by the increased strain of the heavier and stronger motor upon the structure. The machine was finally put into production and then abandoned after the test of July last, and after an expenditure of more than \$6,500,000 and the loss of several valuable lives.

The overload placed too great a strain upon the wings, and this, with bad construction, compelled the board to stop production. The money loss may be partly recovered by salvage. The loss of life and of months of precious time through the need of substituting another type of plane for the Bristol and then producing it are matter of far more serious concern.

#### The Spad Contract

In September, 1917, the Signal Corps contracted with the Curtiss company for 3000 one-seated Spad planes. This is an excellent French biplane, then and now in use on the front. In October the contract was canceled, the reason given therefor being that it was done at the direction of General Pershing. Inasmuch, however, as General Pershing's cablegram concerning the subject bears the date of Dec. 14 following, we must accept the statement of the Curtiss company's officials that the board canceled the contract because it desired to equip the plane only with the Liberty eight-cylinder motor, which was found impracticable. The Liberty 8 was about that time discarded.

The plane was too light for the Liberty engine, so its production was suspended. The French use the Hispano-Suiza motor with this plane, and the Curtiss people assure us that their contract would long ago have been completed and the planes

in the service at the front had the manufacturers been permitted to proceed with production. No attempt was thereafter made to manufacture single-seater fighters, ostensibly because of the Pershing cablegram, until May last, when Mr. Ryan placed an order with the same company for 1000 SE5 planes. This is substantially the English equivalent of the Spad and will probably be in production during the coming autumn. It is manifest that if the manufacture of the SE5 is proper at this time, then the discontinuance of the manufacture of the Spad was a mistake, regardless of who is responsible therefor.

The plans for the Caproni and the Handley-Page bombing machine were available to the board soon after our entry into the war.

#### The Caproni Episode

Early in the summer of 1917 the Standard Aircraft Co. was instructed to hold its plant at Elizabeth, N. J., in readiness to build Caproni planes.

About Sept. 15 a verbal contract was made with the Curtiss company, formally confirmed on Oct. 8, 1917, to build 500 Caproni planes. This contract was never carried out, because no information was furnished to the Curtiss company, although it repeatedly endeavored to secure the same. Afterward it was canceled, and contract for the Bristol Fighter was substituted.

As early as October, 1917, at an international conference in Paris concerning a general aviation program, the Italian inventor, Caproni, was summoned to meet Colonel Bolling, one of the heads of the aviation section in Paris. An arrangement was ultimately made by which Captain D'Annunzio and a force of workmen and engineers were to be brought to America to produce in American plants Caproni machines. Captain D'Annunzio and nineteen of the best men of the Italian factory arrived in the United States on Jan. 17.

In January, 1918, the Standard company was given a verbal order for 1000 Capronis, fifty to be assembled and 950 to be sent overseas knocked down. Drawings were prepared, but no official order was given for the machines.

On Jan. 25 Captain D'Annunzio and his men came to the plant, began work on a hand-made machine. A witness describing the transaction states that—

"They (the aeroplane authorities), in February, began to back and fill on whether they were going to build Capronis in quantity, and by March 2 it was practically settled that they would not build Capronis in this country at all, except the ones we were working on and two or three for experimental purposes.

"As a result of that we took the Handley-Page as a substitute."

Captain D'Annunzio states that he had expected upon his arrival in this country that everything would be ready. "They were wiring and cabling Italy, asking for the engineers of the Caproni plant. I requested General Tozzi, who is head of the Purchase Mission in Washington, to help me clear up the matter. So we pro-

voked a lot of meetings between myself, Colonel Deeds and some other officers. \* \* \* It was just the same as before, because no decisions were reached. \* \* \* I found they were undecided as to whether they should make that machine, although demonstrations had been given before the European Military Mission," etc.

Finally Captain D'Annunzio was authorized to build the first experimental machine for American engineers. That machine was finished and flown on July 7. In the meantime, and about April 12, the Fisher Body Co. obtained an oral contract for 250 Capronis, which was later canceled. Again, about May 18, 1918, the Curtiss Aeroplane Co. was given an order for 500 Capronis, and on the same day the Fisher Body Co. was given an order for 500 Capronis. It is understood, however, that nothing will be done to carry out this order until the experimental machine has been tested out. This precaution is proper.

During the interval of delay both of the Italian pilots who came to this country were killed in other machines, and the Caproni program is now awaiting the arrival of Italian pilots and the testing of the experimental machine.

Over 12 months of time has been thus consumed since the Caproni came under serious consideration.

#### Handley-Page Offer

Plans for the Handley-Page machine were supplied to the Signal Corps in the summer of 1917 by the owner, with full permission to use them. Its engineers made a number of changes in them, beyond which nothing was done with them. Hence, the representative of the owners in the early winter demanded their return. They were delivered to him as changed.

In February last contracts for 1000 sets of parts, afterward reduced to 500 sets of parts, were made with various contractors, to be assembled in Great Britain for the use of the American Army. From 60 to 90 days are required for the assembly of a Handley-Page machine. Twenty of these have been embarked, and we are informed that they will continue to go in constantly increasing quantity, reaching 140 for the month of February. Had these contracts been let last October they could have been completed and delivered by the 1st of July.

One sample machine constructed by the Standard Aircraft Corporation was completed and given its initial flying test on July 6 last. If further tests prove satisfactory the design will go into quantity production. Had the machine been ordered last summer it should be in quantity production now.

#### 1200 Planes Discarded

The production of training planes has been fairly adequate. One type, the Standard, of which there were 1200, has recently been discarded because the Hall-Scott engine which drives it has proven unsatisfactory, but there is no reason to apprehend that training plane production will fall below the requirements of the

service. The designers and manufacturers of this plane insisted that with a good engine it is all right, and this insistence will be tested. If successful they can be made available hereafter. But General Kenly and his assistants found them highly dangerous because of the motor and ordered their retirement. The machines cost the Government about \$6,000,000.

#### The De Haviland 4

The De Haviland 4 is the only so-called fighting plane now in actual production. Outstanding contracts call for 8500 of them. They are being manufactured by the Dayton-Wright and the Fisher Body companies, with smaller contracts to the Standard and one or two other producers. On August 1 a total of about 1000 of these had been delivered, all but a few of which had been turned out by the Dayton-Wright concern.

The first plane of this type was embarked for France during the latter part of February of this year, but never reached port. Up to July 1, 286 had been shipped abroad, of which 67 had reached headquarters in France. On August 1 601 had been embarked. A number of them were delivered to Gen. Pershing's headquarters in June, and upon inspection were found to contain many defects, some of which were serious, others of less importance. Under date of June 26 General Pershing cabled the War Department enumerating many defects and stating explicitly that the machines could not be used until some of them were corrected. Also that all planes of this class should be thoroughly tested and inspected before being shipped to him. This obvious requirement General Kenly had insisted upon observing, but sent them over in the instance considered without doing so, because of an overseas order requiring it.

#### Defects in De Haviland 4

Some of the defects enumerated in this report, in the opinion of every expert flyer who has been examined by the committee, rendered the machines more than ordinarily dangerous. Their opinion differed as to whether or not corrections can be made to make the machines safe, but the assertion that the plane is very unsafe in the condition in which it has been up to this time delivered from the factory was practically unanimous. Deliveries of the machine continued notwithstanding, and many were sent to France in precisely the condition complained of in Gen. Pershing's cable. The explanation offered for continuing delivery of these defective planes is that the corrections could be made overseas, and a force of American officers and mechanics under command of Lieut. Col. Hall was dispatched to France about the middle of July with orders to make them. Your committee is of opinion that the planes should never have been permitted to leave the factory in their defective condition, and the fact that they were permitted to go shows either a lack of appreciation of the situation, a disregard for it, or a very poor system of inspection. On August 2 an order was issued

to all the factories directing that no more of them be delivered until the corrections required were made. We are informed that production under these new conditions is about to be resumed.

In July 155 of these planes were delivered to the Navy, about 50 of which were shipped abroad and approximately 100 crated and delivered at the seaboard for shipment. At this stage four of them selected from the lot were sent to the Navy testing field at Miami, Fla. A test and inspection there revealed the same defects that were reported by General Pershing and some others. The commandant, Capt. McCaughtry, immediately reported this fact to the Navy Department with the result that a cable was sent to Admiral Sims apprising him of the defective condition of those previously sent, while the 100 in crates at the port of embarkation were rejected and returned to the Aircraft Board.

Forty De Haviland 4's sent to a Long Island Field about this time and tested out in the vicinity of New York were pronounced structurally weak and defective. With the production of the De Haviland 4 it has been the same story of changes. Many of these have been made in the plane since the board determined upon its manufacture. Some were unimportant, some extremely so; many of them undoubtedly necessary to its adaptation to the Liberty motor. But they have been made for the most part by automobile and mechanical engineers, having little or no experience in aviation engineering.

#### 54 Perfect Machines Delivered

On the 28th, 29th and 30th of July three squadrons of 18 machines each, 54 in all, having been overhauled by American and French mechanics at an American aviation base behind the French lines, were delivered to the front under their own power. These planes are said to have received the approval of Capt. de Haviland after a careful inspection. Assuming this to be true, it indicates that the machines sent over have been carefully inspected and the defects remedied. On August 7 one squadron of these, comprising 18 machines, under command of Gen. Foulois, made an expedition across the German lines and returned in safety to their base. This marks the date of the use of the first American-built plane over the enemy's lines. The committee has no information regarding the character of their performance.

The character of the evidence concerning this machine, ranging from qualified approval to severest condemnation shows that the De Haviland 4 is chiefly available for observation or reconnaissance purposes. That the War Department and the Aircraft Board share this view is best evidenced by the fact that it is to be replaced by a machine of later design as speedily as may be possible without complete suspension of production.

With the exception of the S. E. 5 and the Handley-Page, in parts, no other type of fighting plane can be produced in quantity before 1919.

The U. S. D. 9 plane is a redesign of

the British D. H. 9, being a great improvement on the D. H. 4. But the U. S. D. 9 has not yet fully responded to the tests of the military bureau and will go into production only when it does so. The U. S. D. 9A, another and later design, now under test, promises to be a satisfactory machine. If the promise is fulfilled by the test, the design will be adopted and substituted for the De Haviland 4.

Recognizing the fact that the United States would not produce planes in quantities early in the war, the board contracted with the English and French early in 1917 for a supply of fighting planes. Of these 2,114, according to the latest testimony we were able to receive, have been from time to time delivered. This enabled us to maintain 13 squadrons of 18 fliers each on the front, a force which is wholly inadequate to meet requirements of modern warfare. It should also be stated that as our troops are moving to France in great numbers, the disparity may increase until we get into quantity production. It is proper to call attention to the fact that at an investigation of the War Department by the Military Committee, held in January and February, 1918, the committee was assured that the French could and would furnish all the combat planes we needed, provided we would send them the raw material, and that this material was being furnished. This assurance was given when the committee showed anxiety at the continued delay in the shipping of planes.

In January General Squier and Colonel Deeds testified to this fact and Secretary Baker gave similar assurance to the committee. The facts, however, are as shown by the testimony of General Kenly, given on July 20, that the plan failed for two reasons. We quote his testimony:

The French contract practically fell down, as you know. \* \* \* It was due to what I consider two reasons. In the first place, the contracts with the French were dependent upon the sending of raw material that was to be furnished by us, and we did not live up to our agreement. \* \* \* In the second place, the increase in German activities in the air caused a change of program in French aviation construction. \* \* \* The French contracts fell down, so that we became more or less dependent upon what could be furnished on this side.

Besides this, many of the machines our men are now forced to use in France are unsatisfactory, but not more so than those used by the French themselves. An Army officer recently at the front testified that the American troops are using many antiquated machines purchased from the French that were discarded by them a year and a half ago. They are using the Sopwith 1½ strutter, which has been declared unsafe by the French and British for observation work. They are using the A. R., equipped with Renault 220, which has a ceiling of only 10,000 feet. They use a Spad two-seater, which is unreliable and unsatisfactory. They were using a few French Briquet machines and the Sampson, which is a

French machine. It is therefore reassuring to reflect that all commands are unified in France, with all lines of the service under a common protection.

### Praises Liberty Engine

The Liberty 12-cylinder engine is an excellent one for the heavier planes and certain other purposes. Its weight of 825 pounds and its 400 horsepower makes it too heavy and too powerful for the lighter types. It is not yet perfect, but it is improving under repeated tests and experiments, which disclose defects for elimination and suggest changes and readjustments of its parts. It is now in quantity production, more than 4,000 having been delivered, and it is approved by our allies, who are anxious to obtain more of them than we can at present supply.

In the development of this motor the Aircraft Board has performed an important task, for which due credit should be given. But the announcement that it had been evolved in a few days was unfounded, and the notion which was encouraged that it could be used for planes of all sizes and character was largely responsible for delays to our plane program.

Motor production has proved to be a formidable task, magnified in some degree by the reluctance of the designers to promptly accept and act upon suggestions of imperfections from competent engineers and critics and fliers and make changes in conformity with them.

### Making Foreign Engines

The manufacture of the best foreign motors, among which are the Rolls-Royce, Hispano-Suiza, and Fiat, contemporaneously with the development of an American engine would have been the sounder policy. That it was partially adopted later confirms this conclusion. We are doing what should have been done a year ago and are producing a 150 and 180 horsepower Hispano-Suiza motor in quantity. Deliveries of the Le Rhone, Bugatti, and 300-horsepower Hispano-Suiza will follow.

American concerns are making the Rolls-Royce motor for the British Government and should long since have been making them for ours. The smaller types of Hispano-Suiza are serviceable for the lighter and faster planes. In view of these conditions, the apprehension of a year ago that we could not produce foreign motors in quantity because of their metrical measurements and intricacies of construction, requiring manual instead of machine work, which we did not possess, becomes untenable.

No fighting plane of American or other design has been built around the Liberty engine, although it is an axiom in aeronautics that planes must be adapted to motors. The Aircraft Board authorized some attempts at this all-important work, one by Capt. Le Fere and one by Col. Clarke, the first of which is being tested and developed by the board, with good prospects of success. This should have been done before, as the type must be made effective before the best performance of the Liberty motor can be secured. A Curtiss design also gives promise of

satisfactory results in the near future. The motor can be used in some other models with good results, but until a Liberty plane is successfully built around a Liberty motor by competent aeronautic engineers and thoroughly tested out our air program will not be complete.

### Poor Inspection System

The Signal Corps inspection system has paralleled that of the producers. In some instances it has functioned badly, with the result that defective material has at times been accepted and material condemned and reported to chief inspectors has found its way back to the producer. In some factories the finished product has been accepted, although not up to requirements. Generally speaking, the production and inspection systems of the manufacturers seem to be more co-operative than competitive. We have found no collusion between the official and the private inspector, but the inspection in the past has been bad. The faults of the system are in part due to the incompetency of the inspectors. We are informed that the system has undergone and is now undergoing a radical transformation and is being remedied as rapidly as skilled and efficient operators can be secured.

### Our Training Fields

The training fields are each designed for 600 enlisted men, 300 cadets, and 72 officers, a total of 972 men, which, owing to the exigencies of the service, have at times been exceeded. This arrangement requires a total of 54 structures of all sorts for each standard field. In addition to these, there are repair and supply depots, balloon schools, experimental stations, radio laboratories, warehouses, quarantine camps, temporary barracks, photograph schools, etc.

Up to May 25, last, there were 31 fields, including balloon schools and experimental stations, and 37 miscellaneous projects comprised in the above recital, not including the training schools at various State and other universities, nor projects recommended but not yet approved by the War Department. Their estimated cost is \$52,511,134, of which \$39,356,407 have been expended, exclusive of a field at Miami, Fla., established by Co. E. A. Deeds, a member of the board, on his own responsibility (and without the knowledge or sanction of the head of the equipment division having charge of the work), and a night flying route from Dayton, Ohio, to Rantoul, Ill., by way of Indianapolis. The cost of these extra projects was over \$400,000. This night flying route was used for the first time on the night of August 12 between Dayton and Indianapolis, and was pronounced satisfactory by Gen. Charles E. Lee and Capt. J. Fitz Morris, of the British air service, and the aviators who made the trip.

The Equipment Division had some difficulty in securing material for construction prior to the advent of Mr. W. C. Potter, now assistant director of the Production Board, since which time there has been much improvement.

The contractors for the work at Lang-

ley field and the fields at Dayton were not satisfactory. Upon the whole, the work of construction proceeded fairly well and the structures on most of the fields have been completed.

Langley Field, near Newport News, Va., consisting of 1,650 acres, was selected prior to our entry into the war for a training and experimental field. The estimated cost of its needed buildings, not yet completed, is \$3,664,050, of which \$2,305,697 have been expended. It seems to have been wisely chosen and well fitted for testing and experimental work.

### Dayton's Flying Fields

Nevertheless, it was practically abandoned last year for that class of work, and McCook Field, at Dayton, Ohio, consisting of but 200 acres, and practically inclosed by river, trees, and telephone and telegraph wires, was selected instead and leased at an annual rental of \$12,500. The reason assigned to the committee for this change was the lack of transportation facilities at Langley, although a spur connecting it with nearby railway systems had been constructed by the Government for its express accommodation prior to the transfer. The insufficiency of this reason is emphasized by the fact that about the same time the board selected the Wilbur Wright training field, near Dayton, requiring the construction of a trolley line by the Government, at a cost of \$175,000, which is its only line of transportation. The field is now being used by the Bureau of Aeronautics for its military testing plant. McCook Field is not only too small for satisfactory experimental flying, but its environment is unfavorable to its use for that purpose. The board has, however, equipped it with structures costing \$920,100.

Adjoining the Wilbur Wright Field is a large warehouse, built at a cost of some \$500,000. In this warehouse are stored great quantities of supplies, many of which, like machine guns, radio batteries, photographic accessories, etc., are manufactured in the East. To send them hundreds of miles west for storage, re-shipping them over the same route back to the seaboard when needed for overseas uses, is waste. It needlessly adds to railway congestion and should be corrected.

Your committee visited but a few of the training fields, of which Wilbur Wright Field, above referred to, was one. It comprises 2,200 acres and belongs to the Dayton Conservancy Association, and is designed as a part of the bed of a great reservoir to hold back the flood waters of Mad River. Much of it is low and swampy, either on a level with or slightly above the normal level of the stream flow. Any considerable rainfall floods a great portion of it and a rain of 36 hours last March caused an overflow of nearly 2 feet above the floors of the hangars, thus seriously threatening the planes with damage and suspending training completely. A drainage system, since installed, is said to have improved this condition, but your committee is informed that the Signal

Corps was advised by competent authority against locating a field upon these premises because of its low and marshy character, and the judgment of the officers and fliers at the field and familiar with the ground was a unit against its adaptability. An excellent stretch of ground within 4 miles of this field, traversed by railway and high above the river level, admirably drained by nature, was available to the board when Wilbur Wright Field was selected.

The large sums expended upon the Dayton-Wright Field, amounting to \$2,878,699, and requiring an ultimate total of \$3,097,777, and its use for testing purposes, probably demands its present retention if the drainage system referred to shall prove fairly effective. But when the dam is completed—the reservoir is to be filled—the buildings must be removed, or they will otherwise be submerged.

More recently the board, desiring an additional field near Dayton, was offered an acreage adjoining the Dayton-Wright Airplane Factory on the east. Inasmuch, however, as insistence was made that the lease be executed to the Dayton-Wright Co., as lessee, for the use of the board, the rental to be made an item in the cost of airplane production, the representatives of the board very properly declined the suggestion, and the project is still incomplete. We feel obliged to note in this connection that shortly before negotiations for the McCook and the new field, Col. E. A. Deeds, a member of the Aircraft Board, was the owner of the first and a part owner in the second. He sold and transferred them to interests with which he had been identified, and which now own them.

#### Aviation Contracts

At the outbreak of the war but few concerns were engaged in airplane and motor construction; but there were concerns devoted to other pursuits, and potentially capable of producing both in quantity if encouraged to do so. The need for planes in volume, and as rapidly as possible, prompted Congress to make the largest single appropriation for the Signal Corps which up to that time had ever been made. Since then our engine-producing capacity has been fairly enlisted, while that of plane production has not been properly encouraged. A number of plane manufacturers, like the Wittmann-Lewis Co. of New Jersey, and in the business years prior to the outbreak of the war, have been unable to obtain contracts; while a number of concerns like the Dayton-Wright Co. and the Standard Co., have been practically organized since the war, and the former was given enormous contracts before its factories were completed.

Companies assured of capital and factory space have been denied contracts because they were not going concerns, while other companies in similar condition have received contracts, notwithstanding their present lack of producing equipment. No one official controlled or supervised the making of agreements or their execution. Beginning and ending with the Aircraft Board, the head of production,

the director of supplies, the head of the contract section, and perhaps other links, made up the chain of procedure. Adopting models of proved efficiency, and then putting all responsible producers at work upon them, would, in the opinion of your committee, have greatly expedited, as it would have guaranteed, the performance of the aircraft program.

#### Money for Makers

To aid in the construction of the Dayton-Wright plant and the Elmwood plant of the Curtiss Co., the board made generous advances of money, and to them was given the task of making and supplying other contractors with plans, designs, blue prints and specifications for the accepted types of machines, exclusive of bombing planes. This gave these concerns great advantage over their competitors, which thus became dependent upon them for material without which the work of production could not begin, and when begun was subject to suspension and delay, with changes in construction and design. Moreover, the Curtiss Co. exacted a fee for copies of plans, etc., of 1 per cent upon the contract price from other contractors, which, although added to the cost of production, was paid to the Curtiss Co., adding a considerable aggregate sum to its revenues.

The number and amount of contracts for planes and motors assigned to concerns at Dayton and Detroit, and the number and character of aviation fields at Dayton could not fail to attract the attention of your committee. Due to her vast automobile industry, Detroit doubtless possessed greater facilities for gas-engine production than any other American community, and the Fisher Body Co. was well equipped for the manufacture of planes in quantity. A generous recognition of these facts was therefore inevitable.

But Dayton possessed no such advantages. Her manufacturing interests were for the most part in other directions. Industrially considered, the concentration of the greater part of the new pursuits in these two cities may perhaps be justified, but the committee is forced to the conclusion that the personnel of the Aviation Board, from its formation to its reconstruction, explains the fact.

#### Blames Aircraft Board

The civilian personnel of the board, and their more prominent subordinates, were composed of gentlemen a very considerable number of whom lived in these cities, and before or at the time of entering the Government service were leaders in and identified with the industrial development of their respective communities. The divestiture of their interests by transfer to others was a laudable though essential step toward qualifying them to public service, but the granting of major contracts to old associates, the transfer of the experimental station from Langley to Dayton, and installing it upon an inadequate tract quite recently the property of a member of the board, the tender, and qualified acceptance, of a second field formerly owned in part by the same member, the selection of the

Wilbur Wright Field, physically and geographically unsuited for the purpose, and the giving of huge contracts for airplanes to a corporation created since the war began, of which he was one of the first officers, and owned exclusively by his former partners and business associates, have provoked, and we think justly, much of the public comment which made the investigation imperative and much of the resentment of less favored manufacturers in other localities. It is also a distinct argument for those who assume to fear, and who assert, that aviation, through the board, is to be made the subject of ultimate automobile control. This feature of the subject is, as heretofore stated, under full investigation by the Department of Justice.

#### Against Cross Licensing

Although this subject has been referred to a special subcommittee for investigation, it has constantly obtruded itself upon our attention, hence we can not avoid referring to it.

The National Advisory Committee of Aeronautics, confronted with the necessity of satisfying the claims of patentees and avoiding possible delays threatened by conflicting patent rights, determined upon mature consideration to settle these difficulties through the agency of a Manufacturers' Aircraft Corporation, to be composed of those engaged in the industry and empowered to license all aircraft contractors, who should pay a royalty to the company upon all planes and parts to be constructed and to assign to the company for the common use all patents or applications therefor owned or controlled by the licensees. The bulk of these royalties was to be paid to the Curtiss and the Wright-Martin Cos. as compensation for the use of certain patents until each had received \$2,000,000. These were to be charged against cost of production and paid by the Government. The agreement was sanctioned by the Department of Justice and approved by the Secretaries of War and the Navy.

The committee has not heard a word in approval of it. It is condemned by every airplane manufacturer outside of the immediate beneficiaries. Those executing the license agreements have done so under protest because the Aircraft Board recommended or required it.

Criticisms of it are numerous, the most serious of them being that it subjects manufacturers to onerous requirements by its beneficiaries, such as assessments for the use of plans and specifications, the purchase of the material and accessories from favored houses the assignment and surrender of valuable patents and patentable devices of the Aircraft Association upon terms prescribed by itself, the discouragement of invention, and the inevitable control of the aircraft industry by that association or by some other interest through its agency. Your committee sympathizes with many of these sentiments, and notwithstanding the Aircraft Production Board as now officered no longer requires or recommends the execution of the agreements

by contractors, we believe the arrangement should be abrogated. We regard it as vicious and as designed to reap large profits by taking advantage of the necessities of the Government. The basic patentees should, of course, if the patents are valid, be compensated, but this should be done by the Government directly whenever the courts finally determine who the owners are and the patents should then be made free to all manufacturers.

New patents of meritorious character should be similarly acquired by the Government as they appear. Such a course would stimulate invention and promote the development of an art which is still in its cradle.

This is not a new departure but rather a reversion to an original policy, for Congress in 1917 appropriated \$1,000,000 for the purchase of aircraft patents, which sum is still available, and if insufficient for the purpose it can be easily increased. The Government should never be made the victim of a patent monopoly which it generously created for the sole protection of the inventor against infringement by persons and corporations.

#### Production Difficulties

Much can be said in extenuation of the disappointments encountered in aircraft production. The industry is new and highly technical. Mechanics skilled in the art were few when the war began, and of aviation engineers there were scarcely any. Production capacity was undeveloped, and even planes for training were not immediately obtainable. Up to January, 1917, only 118 airplanes of all types had been delivered to the Army, 64 of which were made in 1916, and there was no aircraft organization either in the Signal Corps or out of it. The Bolling Commission was not sent to Europe until June, and its report was not received until September. But for the glowing forecast and optimistic announcements which the board and others made to the public from time to time regarding its actual and prospective performance, and the certainty of speedy and unlimited production, public disappointment would not have been so pronounced nor public resentment so widespread. Great Britain in 1915 and 1916 experienced delays, miscarriages, and expenditures. Instead of profiting by her experiences the board incurred similar ones and accentuated them by representations and assurances which were not warranted by the actual facts.

The order of the President creating a Military Bureau of Aeronautics and a Director of Aircraft Production and the appointment of Gen. Kenly and Mr. Ryan as the heads of the two divisions is an improvement upon the previous situation, and a number of the conditions we have criticized have been or are in the process of being corrected and better methods instituted. For example, a single board of engineers formed by combining the technical and production engineering sections and headed by a chief selected by Mr. Ryan, with the approval of Gen. Kenly, has been established; one testing

board under the command of a single officer has succeeded the double system formerly doing the work. The Military Bureau, under agreement with the director, after thorough experiment by actual fliers and aeronautic engineers, now determines the character of machine to be produced, and the business of the director is to produce it.

#### Committee Recommendations

1.—The inspection of the finished product and other material is now the work of Gen. Kenly's division and is to be done by thoroughly competent officers. Work not satisfactory to Gen. Kenly or not up to the requirements of his Bureau is rejected. Co-operation for the common end has been, and we hope will be, observed by the heads of the two divisions and required from their subordinates. The loose ends of the former organization have been gathered up as rapidly as possible, and the results of the improved conditions are already apparent in some directions. But the system is still subject to the criticism that it is dual in character, which is unsatisfactory, since it may at any time lead to differences and to division of responsibility. We are constrained, therefore, to renew the committee's recommendation of last April, sustained by the opinion of every man whose views were consulted by us; that the whole subject should be under the control of one man. Our present organization is faulty because divided into two parts with a man of strong will and opinion at the head of each division. While these two divisions are correlated, they may not be permanently co-ordinated. Your committee therefore believes that the importance and magnitude of aviation as a permanent branch of our military organization requires one directing and responsible head both for its efficiency and speedy development. Its classification with the Army and Navy as a distinct arm of the service is essential to this end.

Of comparative insignificance at the outbreak of hostilities in 1914, aviation has become indispensable in modern warfare. Without aircraft no army can any longer hope to triumph or, indeed, to escape inevitable defeat. Without aircraft the most powerful navy must in these days remain upon the defensive. The aircraft force of Great Britain and France each outnumbered the regular army of the United States when we declared war, and ours should soon be as large as theirs. It is a distinct arm of the service. Great Britain and France, recognizing its supreme importance and the need of its swift expansion, last year each converted it into a department of its own, whose head, as minister of the air, ranks as an officer of the cabinet, who is held responsible for efficiency of production and manufacture and an efficient force of aerial fighters. We should do likewise—create a department of aviation, under the control and supervision of a secretary, and ranking with those of the Army and Navy. We would thus place power and responsibility in the hands of a single man, organize a service

not alone for this war but for all time, and establish for the forces of the air the same policy of administration that has so long governed those of the land and of the seas.

The cost of equipment and maintenance is rapidly approaching that of the Navy, while training for aviation is as distinct and as technical as that for West Point and Annapolis.

The creation of the department of the air would unify the service, thus removing all friction between the Army and the Navy divisions of the service by subjecting both to the control of a common head. Differences between them under present conditions are unavoidable and, while more disagreeable than serious so far, they will arise from time to time, tending to seriously disturb the service, besides interfering with production.

2. A commission of engineers and pilots for observation at the front, formed in relays and reporting in person to the department at frequent intervals, is also imperatively demanded. The betterment of the air service through the exigencies of actual warfare is rapid and important. They should be accurately and promptly reported in detail to the home office, and this can be efficiently done in no other manner. Similar conditions have long been maintained by our allies, whose policy in this regard we will do well to adopt.

3. But your committee feels that the prime need of the hour is machines in continuing quantity, and the production of them should be accelerated by enlisting the constructive activities of all responsible concerns engaged or which can be engaged in the business to full capacity. We cannot, while the war lasts, have too many effective planes. Supremacy of the air means a speedy triumph. We have hundreds of trained pilots waiting for planes, whose services must be postponed for their production.

Planes to be useful must have motors. These too should be in production in every factory that can and will turn them out, due allowance being, of course, made for other equally insistence requirements for ordnance, ships and the like. If this is done, the results for 1919 will then compensate somewhat for the disappointments of the current year.

4. The rapid development during the war of the aeroplane and its effective use as an important arm of the military makes it imperative that America give greater attention to the perfection and production of aircraft. This should be done not only as a war measure but as a commercial and industrial necessity.

The importance of a powerful air force, and an abundance of heavy artillery cannot be overstated in bringing the war to a speedy and successful conclusion. With our vast resources in raw material and our facilities for manufacture we can, by the adoption of a broad program and with the assistance of our allies, obtain the complete supremacy of the air.

Without hesitation or delay we must give attention to this expansion of our aircraft policy. The inventive and pro-

ductive genius and energy of America must be devoted to the creation and improvement of new types of aircraft and engines. Our present program must be greatly enlarged. The United States should establish at Government expense college and university courses in aero dynamics and mechanical engineering, in addition to courses for training fliers.

While quantity production is essential to the complete equipment of our armed forces, quality should not be sacrificed to quantity. The aeroplane requires the highest degree of skill in workmanship and the very best kind of materials.

The aeroplane is a product of American genius, but the credit for its development largely belongs to other nations. America should meet this challenge by bringing the aeroplane to still greater perfection.

5. The inventive genius of the nation should be encouraged in the most effective way. A Bureau of Inventions, recently established by the War Department, is a step in the right direction. A persistent complaint, doubtless in a large degree due to the disappointment of men whose devices have not been pronounced practicable, is that under the administration of the old board scant consideration has been given to new devices and suggestions. This seems principally to have resulted from the absence of any well-defined individual agency having full authority to deal with the subject. One man, the designer of a model for a dirigible with a car integral with the Blimp, began with the Advisory Committee and was passed on from one officer to another until he finally completed the circle and was referred back to the committee which started him on his journey. About six months were consumed in making the circuit and nothing was accomplished. A plane designer encountered a similar experience, with the added one that his plane was crushed to pieces in a sand test which was declared satisfactory by those who made it but wholly unsatisfactory by those empowered to make final decisions. Many, perhaps most, of the so-called inventions brought to the notice of the authorities in times like this are of no importance. But if the germ of something new and useful can be detected in one of a multitude of models, the time and energy expended in discovering it will redound to the benefit of the nation.

6—Ample protection should be extended by the Patent Office to applicants for patents for inventions relating to the public welfare and defense. This is demanded not so much for the inventor as for the nation. Authority for this now exists, but it seems to be exercised at times and disregarded at others. Additional legislation may be necessary to make this precaution effective, but in the meantime a suggestion from the Production Board to the Commissioner of Patents regarding applications for inventions relating to aircraft would doubtless shield the application from all publicity, thus assuring its indemnity against disclosure to enemy interests.

7—The margin of profit on some con-

tracts, particularly for motor production, is altogether too high. According to the estimates of the accounting division they appear to be for the Liberty motor at one of the plants 33.6 per cent; for Liberty engine aluminum pistons, 285 per cent on capital invested; for the Le Rhone, 92.8 per cent on cost of production; and on the D. H. 4 plane about 50 per cent. This is largely due to the primary unfamiliarity of officials with the cost of rapid manufacture of novel products in great and urgent demand.

The high cost to the Government having been now demonstrated, we feel sure that future contracts will result in great saving to the Government.

8—Planes and engines rejected because of defective construction or materials not furnished by the Government direct should be at the cost of the producer. Existing agreements require payment from the Government for everything delivered, presumably because they have passed official inspection. But when producers are required under their agreements to bear the expense of an inferior product, on the perfection of which human life is absolutely dependent, their own inspection will be of the best, and good workmanship will inevitably result.

9—Your committee, in inspecting the aircraft plants have noticed the great danger of destruction by fire owing to hazardous processes of manufacture, hasty construction, lack of automatic sprinkler and other fire protection.

The burning of any of these factories in whole or in part at this time would be a catastrophe, for it would greatly cripple the aircraft program.

We urgently recommend that the requirements of the Fire Prevention Bureau of the National Council of Defense, composed of fire insurance experts, for better fire protection in these factories be made immediately compulsory by the Director of Aircraft Production, and that a stipulation be inserted in future contracts compelling a compliance with such recommendations.

#### Gasoline Conservation Requested

(Continued from page 379)

greater than the July consumption of 1917, while production was 27 per cent greater than in July of 1917.

The request calls only upon the owners of cars east of the Mississippi River because those west of the river are in or close to the production field and are not affected by the transportation problem which is another factor. Transportation east of the river is devoted so largely to war work and to carrying oil and gasoline for shipments overseas that some eastern localities have already encountered serious gasoline shortages.

The Conservation Department of the Fuel Administration points out that there are over 5,000,000 automobiles in use in the United States, and that if each passenger car owner will do his utmost to conserve gasoline, preventing spills, racing of engine, etc., each owner can probably save from  $\frac{1}{2}$  to 1 pint per day, which in itself would effect a sufficient saving to meet the excess demand.

The Conservation Department plans to establish oil conservation districts throughout

the country, placing automobile dealers at the head of each district together with committees to be composed of newspaper men, automobile club representative, oil industry representatives, garagemen and dyers and cleaners. These committees will in turn appoint deputies for each county. Huge posters will be displayed everywhere, and all garages and oil stations will be instructed in every means of gasoline and oil conservation. The Fuel Administration is desirous of securing conservation of oil and gasoline without issuance of any direct orders, and is adopting the plan of intensive education for that purpose.

Following is the complete statement by the Fuel Administration:

The United States Fuel Administration considers it necessary that a limited conservation of gasoline be undertaken, in the States east of the Mississippi River in view of the increasing demand for gasoline for war purposes and the paramount obligation of meeting promptly and fully all overseas requirements.

An appeal is made, therefore, to the people of the United States east of the Mississippi River to exercise rigid economy in the consumption of gasoline during the next few weeks as a necessary and practical act of patriotism.

War necessities are being and will continue to be promptly and fully met, but this is the period of the year when consumption of gasoline is at its highest, and the increased domestic demands, together with the extensive military operations in France, have rendered necessary, for a limited period, the adoption of safeguards against possible shortage.

In view of the difficulty, if not the impossibility, of differentiating between the various uses to which automobiles are applied, the United States Fuel Administration believes that the greatest measure of economy can be effected with the least interference with the business of the country through the discontinuance of the use of all classes of motor vehicles, motor boats, and motorcycles, on Sundays.

The United States Fuel Administration therefore requests that in the section of the United States east of the Mississippi River there shall be a discontinuance of use of the vehicles above specified, including all such as are operated for hire, on each Sunday hereafter until notification that the need for such discontinuance has ceased.

#### Decreases in Bituminous and Anthracite Production

WASHINGTON, Aug. 27—Less than 12,000,000 tons of bituminous coal were produced for the week ended Aug. 17, the first time that production has been below this figure since June 22. The output was 11,910 tons, 379,000 tons less than the preceding week, but 1,597,000 tons greater than in the corresponding week of 1917.

Anthracite production for the week of Aug. 17 was 1,924,000 tons, a decrease of 127,133 tons as against the preceding week, and also a decrease of 63,800 tons as compared with the corresponding week of last year.

The bituminous mines produced 79.7 per cent of their full-time output during the week of Aug. 10. Car shortage was responsible for a loss of 9.8 per cent; labor shortage, 4 per cent; mine disability, 4.2 per cent; no market, 0.4 per cent; all other causes, 1.9 per cent.

## Why Hudson Dealers Have Faith in the Hudson Future

Talk with a Hudson dealer and you talk with a man who has every confidence in the future. He is satisfied that the Hudson foundation he is building on is a solid one.

He is not only sure of the quality of the car he sells but he is sure of the manufacturing and sales policies behind it.

He realizes more than ever the long-range vision with which Hudson plans.

He knows that no temporary, abnormal condition is going to obscure Hudson foresight and cause hasty, ill-advised decisions.

He knows that in spite of curtailment the Hudson name will be kept shining as brightly as ever — not only by consistent advertising, but by performance in the hands of thousands of users.

Thus, when the war has passed, the crisis will have proved the Super-Six even more thoroughly perhaps than the speedway — hill climbs — and cross-country tours.

Hudson dealers will have a foundation more solid than granite upon which to build their post-war business.

## UTILITY *Protected Foot Rail* HEATER

# NOW IS THE TIME TO PREPARE FOR WINTER

Cold weather will soon be here with a greatly increased demand for Utility Protected Heaters in limousines and enclosed cars.

The Utility Heater is the accepted standard of motor car heating. Its principle is sound, logical and convincing. It insures perfect driving comfort, even in the coldest weather, by tempering the atmosphere of the car to any desired degree. It keeps you warm all over, as though you were in a carefully heated house.

UTILITY Protected Heater—installed in place of the foot rail—is the heater universally recommended by thousands of motorists during the past season—the heater jobbers catalog and the heater manufacturers install as standard equipment.

Ease of installation, attractive appearance, freedom from dust, odor or trouble make it the highly desirable heater. We shall be glad to quote on manufacturers' requirements for standard equipment.

*DEALERS—178 more jobbers than last season are now handling the Utility Protected Heater. There must be a mighty good reason.*

## **Delay in Bombing Planes for War Program**

### **Day and Night Bombers as Essential as Chasse and Reconnoitering Types**

#### **Maker Asserts Small Profits Are Made on Liberty Engines**

### **STORY OF FAILURE OF BRISTOL FIGHTER**

**N**EW YORK, Sept. 5—The Senate subcommittee report on aircraft has served to emphasize the fact that we are little more than starting on our program of building bombing airplanes, which in the judgment of not a few European aircraft students must constitute perhaps a dominating factor in our aircraft activities.

We have made progress in building a type of reconnoitering plane in the De Havilland 4 that is useful in such work, as well as in directing artillery fire and photography, but which as a bombing plane is useless, because of its inability to carry a load of bombs capable of doing any material damage. It is only the bombing planes with bomb-carrying capacity of upwards of 2 tons that can work the havoc that must be accomplished if we are to destroy the factories of the enemy, destroy his submarine bases and break up his lines of communication. We could not accomplish this with fleets of chasse or reconnoitering planes even if we had them in the tens of thousands. We must have the giant night bombers with a long radius of action and also the lighter day bombers with their higher speeds and ability to fly at greater heights.

What we need and must have is a synchronized program on the four leading classifications of air-

planes, namely, chasse or fighting planes; reconnoitering planes, day bombers or night bombers.

The production for all four types should come along together in their correct numerical quantities. Our aerial program is lacking in its completeness unless each of these four divisions is given its due consideration at the proper time. It is poor policy to needlessly stock up with chasse machines and then not be able to take advantage of the gain so accomplished by failure to do the necessary day or night bombing that should follow.

To illustrate: If we put our entire airplane production at 100 per cent and divide it into the four divisions, chasse, reconnoitering, day bombers and night bombers, we might give figures such as: Chasses, 20 per cent; reconnoitering, 15 per cent; day bombers, 25 per cent, and night bombers 40 per cent.

These figures are only intended to indicate how the entire scheme of activity should be divided off according to the necessities of the war. All four must be carried on simultaneously. We cannot spend a year on one class and then take up another. All four are needed now and we should be as nearly equally advanced on one as on any of the others. It is unfortunate that we are not.

The biggest men in the automobile industry who risked in a great many instances great sums of money in order to help make the aircraft program a success are not backward in condemning the Senate report.

At the present time the automobile industry has over \$35,000,000 invested entirely in the manufacture of Liberty engines. The profits on the total number of engines already made cannot as yet be accurately estimated, as insufficient time has elapsed to make complete cost calculations. As an example, however, Packard, which was the first to get into production, made less than 5 per cent on its first order, which was for 600 of these engines. Up to Sept. 1 Packard had shipped 3,169 Liberty engines.

### More Liberty Contracts Offered

In spite of the fact that the Senate report gives the impression that the automobile industry gobbled the Liberty engine business to the exclusion of smaller concerns who were more fitted to do the work, the Government is now using every effort to get the automobile industry to accept additional orders for greater quantities of Liberty engines. The question immediately arises, why does the government not go to the concerns which the Senate report indicates should be the ones to manufacture these engines?

The answer is obvious, since it is well known that only concerns which are highly adapted for quantity engine production can enter the program with any hope of meeting requirements.

As production goes ahead, the cost on these engines is decreasing. This is always the case as the personnel becomes more skilled and the routing of the production is changed to meet the demands for better efficiency. It was for this reason that it has been possible to revise downward the figures on the Liberty engine cost.

As pointed out last week, this started at \$6,000 and was afterward reduced to \$5,000, which was set as the bogey figure. These contracts are now under process of revision to fix the cost price as \$4,000.

### Cost of the Liberty Engine

IT IS UNDERSTOOD THAT A CLAIM IS SOON TO BE MADE THAT THE AUTOMOBILE INDUSTRY HAS BEEN FORCED TO TAKE \$1,000 LESS FOR THESE ENGINES. THIS IS NOT TRUE.

The truth of the matter is that the government according to its contracts is given 75 per cent of any saving below the bogey cost of \$5,000, so that when the cost is reduced to \$4,000 the saving to the government is \$250 per engine, as the \$750 would be turned over to the government, anyway, due to its original contract.

The original Aircraft Production Board has been criticized for making incorrect engineering decisions. This cannot be true, as the original Aircraft Production Board had no executive power. It was simply an advisory board and did not have an engineering staff, such as would be required for making determinations as regards materials and design. An

idea of the limited functions of the board, which was really a clearing house for the army and navy aircraft divisions, may be gained from the fact that out of the total of \$640,000,000 appropriated the board had the spending of \$100,000.

### Delay in Adopting Foreign Types

Considerable curiosity is displayed in the industry regarding the cause of a real delay in adopting foreign types. A careful survey of the situation indicates that there are two real reasons for this. In the first place, the foreign governments, feeling that after 3 years of indecision on our part in entering the war it was unlikely that we would enter immediately heart and soul into the conflict, were rather dubious about turning over their plans to us. It was not until this country really showed that it had entered fully into the struggle with all its resources that real co-operation was extended. There is no criticism attached to this, as it was but natural. Knowing the history of America in the automobile business, French manufacturers wanted to be assured that in giving us all their secrets they were not simply furnishing us with information that would allow us to take a dominant position in the airplane industry after the war. It is known that confidential bulletins to this effect were circulated among the French manufacturers, and it is no discredit to their patriotism or business acumen that this was done. It must be remembered that at that time this country had not fully proved itself.

Throughout the entire situation it must be borne in mind that conditions now are altogether different from what they were 6 months ago. The success of the Liberty engine and its development by the automobile industry have been the real causes which have opened the door of foreign assistance.

### Would Not Listen to Experts

On the other hand, it is claimed that we would not listen to the advice of foreign experts. The testimony of those who had actual experience in foreign manufacture was not seriously heeded, and this accounts for delays in adopting types of planes like the Caproni, which is now proving itself of the greatest value.

RIGHT AT THIS TIME THE PLANE DESIGNED BY THE FRENCH COMMISSION UNDER CAPTAIN LE PERE, WHICH IS CLAIMED BY MANY EXPERTS TO BE THE BEST TWO-SEATED COMBAT PLANE THAT HAS EVER BEEN DESIGNED, IS APT TO BE TURNED DOWN. The reason given is that it necessitates a slightly different manifolding system for the Liberty engine. It is claimed that this would interfere with standardized production, although it does not affect the engine itself in any other way except for the manifolding. In the light of past experience, let us go slowly on discarding a plane which seems to have excellent production qualifications besides giving a performance which is a delight to pilots for speed and climbing ability.

One feature that has been clarified considerably by the report of the subcommittee of the Committee

on Military Affairs, U. S. Senate, is that relating to the troubles with the Bristol fighting plane, which was practically adopted and recommended for production by the committee sent abroad in the summer of 1917 to select the best type of fighting plane to be built in America. The committee selected the Bristol and a sample machine was shipped from Europe to Washington, where it arrived Sept. 1, 1917. At that time the go-ahead was given and the work turned over to Lieut.-Col. Clarke, who had a set of British drawings from the factory to assist him.

### Lack of Co-operation

From that date forward the story of the Bristol development until the cancellation of the contract a short time ago, after an expenditure of \$6,482,000, is nothing but an unpleasant tale of lack of co-operation among the various interests involved, and apparent delays which it is impossible to explain and which the committee making the investigation has made no effort to explain. The following chronology serves as a panorama of the development of the work on the Bristol from Sept. 1, 1917, until the cancellation of the contract.

Before taking up this chronology a few facts regarding the Bristol should be understood. As built in England the fuselage was arranged for a 190 hp. Rolls-Royce engine, but when its manufacture in America was decided upon, the Liberty 12 was selected as the power plant, and in September, 1917, the Liberty 12 was in the earlier processes of development and it was 4 months later before it was emerging from its constant succession of changes.

In fitting the Liberty 12 there was considerable increase in weight, approximately 185 lb. in all. The Rolls-Royce engine weighed 615 lb. and the Liberty 12 would range from 800 lb. up. This increase in weight added very considerably to the pounds per square foot of wing area that the planes would have to carry. The Bristol had a wing area of 450 sq. ft. and with its complete weight at approximately 3700 lb., which included all equipment, it had to carry or support 9.2 lb. per sq. ft. of wing area. If the area of the tail portion were added, this weight per square foot would be reduced to 8.25 lb. This load is very heavy when it is appreciated that the French Spad, from which the English Bristol was an adaptation, has a load of 7.3 lb. per sq. ft. and the D.H. 4, or De Haviland bombing plane, has a load of 6.1 lb. per sq. ft.

### Extra Load Factor in Failure?

It does not appear whether this extra load which the Bristol had to carry was a prime factor in its failure or not, but when the early test flights of the Bristol were made at the Curtiss factory it did not carry its equipment and the machine flew with a total weight of 3000 lb., whereas its weight when fully equipped would approximate 3700 lb.

Perhaps the greatest trouble with the adapting of the Bristol to American ideas and to the Liberty engine resulted from a failure to have experienced, qualified men engaged in the work. It was neces-

sary to make numbers of changes due to the difference of length of the engines, as well as the differences in weight, and there was a lack of good, practical aviation experience in this, the work being done by men who had a lot of theoretical information but were sadly lacking in practical experience.

About the middle of October the best airplane designer, who was a real practical man, left the job, because he was not willing to work with those connected with the Liberty engine program. The work was then turned over to a designer who, while he had a good theoretical education, seems to have been lacking in practical experience.

In addition to this handicap in the question of design, there were not a few other difficulties that caused delays. The work of adapting the Bristol after starting in Washington, Sept. 1, 1917, was moved from place to place, and on Nov. 1 it was decided to ship the Bristol plane and all blueprints to the Curtiss factory at Buffalo, where the work was to be done. On Nov. 17, 2000 of the planes were ordered and the work was supposed to be pushed ahead. The report contains letters indicating delays due to the fact that instead of a separate department being given over at the Curtiss plant for this work, it was for quite a time carried on in the open factory, which resulted in numerous delays.

### Many Other Delays

There were many other delays in connection with blueprints. In one case these were held up for a week when the department was moved from Washington to Dayton. There was another delay when part of the organization was moved to McCook Field in Dayton.

The first Bristol machine was flown at the factory on Feb. 28, and the next day when the wings were removed it was found that two wing beams were ruined where holes for hinge pins had been drilled off, necessitating new wings.

When the Bristol was taken to the flying field on March 2 the wings were damaged on the way to the field. The flying field was in a very poor condition and there was trouble with the oiling system on that date. There was no heat in the hangar, no telephone, no spare parts, or portable tools, and drilling had to be done by hand.

On March 5 the first real flight of 5 min. duration was made, but the plane flew with only 3000 lb. weight, not having any equipment. It had to come down, due to engine trouble, sooted spark plugs, and the landing gear was broken.

It was expected that a new landing gear would be arranged and another flight made in a few days, but it was March 22, or over 2 weeks, before another flight was made. One time there would be no pilots, another time it was bad weather, and another time the field was in poor condition.

On March 22, a 15-min. flight was made.

On March 24, the machine flew 1 hr., attaining an altitude of 10,000 ft. and a maximum speed, with a cross wind, of 121.5 m.p.h. The report does not state whether the machine flew with a 3000-lb. total weight or not on this occasion.

Four days later the Bristol caught fire on the flying field and was badly damaged, and it was on April 5 before a new machine could be had to replace the old one.

While this rather incomplete testing program was being carried out various changes had been made. On Jan. 27, thirty-five changes in construction were approved by those in charge of the work.

The report shows that for periods of 8 days there was very little speed in production due to errors in construction and changes in parts.

While this whole course of development was proceeding the army officials of the Signal Corps seemed to be impressed with the fact that the Bristol was one of the best machines. Extracts from the report show that on Jan. 9, when those in charge of the work were at Buffalo, they reported that the Bristol fighter we were copying was very successful. As late as Feb. 13, another army officer reported that the Bristol construction and design was very satis-

factory on the Western front. It was in March and April when rumors began to leak out regarding the failure of the Bristol plane. Some accidents occurred and various reports were circulated as to the reasons for these. It was the general feeling that the original British machine which was copied was at best a tricky type, but that in the American adaptation these characteristics were intensified, making the machine really unsafe.

The report states that the constant effort to change from the tried-out Bristol principles of design and to inject changes of construction to cover careless workmanship or poor materials were responsible for the failure of the job. This, coupled with a lack of concentrated experienced inventive engineering ability, in perfecting the undeveloped features of design incident to the changes, seems to complete the long list of reasons for the signal failure of the job. The report shows that all changes in design were crude.

## Problems Involved in Bomb Sight Design

**Bombs When Released Acted On by Three Forces, Momentum, Gravity and Air Resistance—Wind May Also Be a Factor—Present Bomb Sights Require the Manipulation of at Least Three Scales and Are Too Complicated**

By a Member of the British Aircraft Mission

THE following notes form a brief discussion of some of the outstanding features of bomb sighting; it is not possible to discuss the question exhaustively in a short article, but it is hoped that the main features are clearly dealt with.

Let us consider a bomb attached to an aeroplane in such a way that its axis is parallel to the longitudinal axis of the machine; the bomb is said to be horizontally suspended. In order to make matters quite definite let us assume that the aeroplane is travelling at 100 ft. per sec. (about 70 miles per hour), is flying at an elevation of 6000 ft., and there is no wind.

### Trajectory of Falling Bombs

When the bomb is released by the pilot it falls to the ground along a curved path called its "trajectory." The forces acting on the bomb are three in number: (1) its horizontal forward momentum, due to a velocity equal to that of the aeroplane to which it was attached, (2) the pull of gravity. This force acts vertically downward and gives the bomb an acceleration of 32 ft. per sec. per sec., (3) the resistance of the air. This force acts along the longitudinal axis of the bomb. The air resistance can not be neglected in the design of bomb sights, but since the effect it produces on the trajectory is not very great, we may, for rough calculations, leave it out of account at first.

Considering then the two first forces, we have a horizontal forward velocity of 100 ft. per sec. and a vertical downward acceleration of 32 ft. per sec. per sec. By

means of the simple laws of mechanics we can make the following table:

Time from moment of release, secs.	Horizontal Travel, ft.	Vertical Travel, ft.
0	0	0
1	100	16
2	200	64
3	300	144
4	400	256
19.4	1940	6000

If we plotted these figures, or even by comparison of the figures themselves, we should see that they conform to the well known curve known as a parabola ( $y^2 = 4ax$ ). Only half the curve is present, since the bomb starts from the apex at the moment of release. The "x-axis" is vertical and the "y-axis" horizontal.

We have therefore established that under ideal conditions of no air resistance, the bomb follows the curve, common to all projectiles, of a parabola.

### Air Resistance Causes Trail

Consideration of the effect of air resistance leads us to the conclusion that the bomb will take a little longer to reach the ground and will not travel quite so far forward as it would under the ideal conditions. It will be easily seen that under the ideal conditions, if the aeroplane kept straight on after it had dropped the bomb, the bomb would remain always vertically underneath the machine, since it is travelling forward at the same pace as the machine. That this is very nearly the case may be proved by watching a bomb drop through a hole in the floor of a machine. It will be noticed, especially at big

heights, that the bomb does lag behind a little. The distance between the point on the ground vertically under the aeroplane and that where the bomb actually strikes is called the "trail" of the bomb. The distance is very roughly 4 per cent of the height from which the bomb was dropped. Thus in our case the "trail" would be about 240 ft. The air resistance, and in consequence also the trail, varies with the type of bomb, being smaller for bombs of a good streamline shape than for those whose shape is bad.

From this it may be seen that the trail of a bomb is a most important factor and must always be taken into account in designing a bomb sight. In the rough outline which follows, for simplicity's sake the trail has been neglected. From tables which have been calculated in England both from theoretical and practical considerations, it is merely a matter of calculation to apply the necessary corrections.

The bomb then travels along a parabola, the apex of which is at the point of release. The bomb sight has got to tell us when we are at the right point for release.

### Effect of Wind

At the beginning we assumed that there was no wind. This is, however, never the case in practice, and it must be borne in mind that the bomb follows not the air speed, but the ground speed of the machine. If  $A$  is the air speed of the machine,  $W$  the wind speed and  $G$  the ground speed of the machine for upwind bombing, we have  $G = A - W$ ; and for downwind  $G = A + W$ . We therefore see that for determining the point of release we must know (1) the height of the machine, (2) the ground speed. The height we know from the aneroid. The air speed of the machine we know from the air speed indicator, but the wind speed is generally not known. How then is the ground speed to be determined?

Three methods have been used from time to time:

(1) A direct observation by stop watch of the time taken to pass between two objects whose distance apart is known.

(2) Observation of the drift of the machine when flying at right angles to the wind.

(3) Determination of the velocity of the wind by observing the movements of Archie gunfire bursts or balloons.

Method (1) is laborious and, involving as it does the use of a stop watch, is not to be recommended.

Method (2) is fairly easy to apply at low heights, but at great heights presents considerable difficulties.

Method (3) is perhaps the ideal method, and, since it enables one to find the velocity of the wind above the clouds, is probably the method of the future.

Any of the methods may be checked by means of the use of a spotting bomb, the "sighting shot" of the rifle range.

### Three Scales to Operate

Up to the present time even the best bomb sight in use has had three scales to manipulate: one for height, one for air speed and one for wind speed. All these three only determine an angle, the angle subtended by the target at the point of release, which is the thing that we are after all the time.

It is probable that in the near fu-

ture the scales will be reduced in number to one, a scale of angles only. Not only will this enormously simplify the work of the pilot, but in addition it will render the application of corrections determined by the use of spotting bombs very much easier.

Having now determined the point at which to release the bomb, we have got to find out how to get to this point, and this is the most difficult part of bomb sighting.

The whole difficulty lies in determining in the air the direction of the true vertical.

It is comparatively easy to keep an aeroplane flying level fore and aft. The difficulty is to keep it level sideways. A pilot will often get one wing as much as 6 deg. down without noticing it and this, at the height of 15,000 ft., will put the apparent vertical over 500 yards to the side of the true vertical. The application of gyrostatic devices is not easy. The instruments are so delicate that they are easily put out of action in the air and also require much attention. In addition they are very expensive. It is probable that the use of a simple sight involving the use of a short period pendulum will prove to be the sight of the future.

The foregoing remarks have given a brief and extremely sketchy outline of the principles underlying a bomb sight. Much ingenuity has to be used in putting the principles into practice in designing a sight. The great features to aim at in bomb sight design is simplicity in design and ease of manipulation in the air. A pilot cannot make use of instruments which require him to go through complicated actions in the air. There is a tendency also from time to time to make clockwork sights; these are based on a fallacy, since the ease of running of the clockwork depends to a quite unknown extent on the temperature of the oil used for lubrication. This introduces such complications as to make the sights useless.

### The New French Tanks

SOME details of the new French tanks have reached us by way of London. They are of small size and have been referred to as mosquito tanks. Their construction is very much along automobile lines. In front sits the driver, protected by armor plate all around except for very narrow slits to give him enough of a view to drive by. A gunner occupies a turret at the middle of the machine, and the armament consists either of a gun or a machine gun.

### An Argument for Protection Against Dust

**A**ND a demonstration of the need for air cleaners. The speed of the tractor has developed many new problems for the designer of farm machinery of which none is more important than the protection of wearing surfaces from dust and mud. The happy medium between these two almost never exists. The speed of the moving parts makes either a more dangerous agent of destruction.

Scale drawings of the Pfalz fuselage in plan and elevation

# Details of the Pfalz Single-Seater

Performance Records Obtained in England—Machine Is of the Plane-and-a-Half with Vee Struts—Body Construction of Plywood Formers and Covering

**I**N the June 6 issue of AUTOMOTIVE INDUSTRIES we published the specifications and some general information regarding the Pfalz single-seater scout. Recently a detailed description of the machine with numerous illustrations appeared in *Flight* of London, from which the following is culled. The description was obtained from a machine at the Enemy Aircraft View Rooms.

About a year ago German aircraft firms began to pay more attention to cutting down head resistance of their machines. Thus the Albatross firm turned out some single-seater fighters, incorporating the Nieuport type wing bracing and the semi-monocoque body of streamline shape. It was on machines of this type that the pilots of the "Richthofen Circus" did much of their fighting. Then there was the Roland fighter, in which attempts were also made at streamlining the body, but which went rather farther and made the body so deep as to serve directly as a support for the top plane. Finally we have the Pfalz, in which streamlining has been carried a little farther still, inasmuch as the attachment of the lower wings takes the form of wing roots formed integrally with the body and the object of which is presumably to avoid sharp corners at the juncture of wings and body. The wing arrangement of the Pfalz also differs slightly from that of the Albatross in that the inter-plane struts do not come to a point on a single lower spar, but are separated at their lower ends by a short horizontal piece, evidently so as to enable the struts to take care of the twisting moment due to the travel of the c.p. better than can be done with a point attachment.

An examination of the Pfalz biplane gives the impression of very low resistance indeed, and with an engine of 160 hp. one naturally expects the machine to have an excellent speed. Tests carried out in England do not, however, confirm this first impression, and the following particulars of performance can only be regarded as disappointing in view of the promising appearance of the Pfalz.

## Performance Criticized

The rather unsatisfactory performance may be explained by figures given in the table. The body appears to be of good streamline form, but against this must be placed the fact that the maximum cross sectional area is comparatively large, owing to the deep body reaching nearly to the top plane. As regards the wing bracing, this is simple enough as far as concerns the number of wires and struts, but the cables are not faired, and as they are of rather large diameter, their resistance at maximum speed may reasonably be assumed to be fairly high. If, however, the detrimental resistance is considerable, the wing resistance is probably no less so, the wing section being of the deeply cambered type so favored by German designers, and which has, generally speaking, a somewhat high drag, although its lift is good.

Constructionally the Pfalz single-seater is even more interesting, showing, as it does, considerable departures in detail design from other German makes of the same class, on which its fundamental arrangement is evidently founded. This refers especially to the Albatross fighter single-seater, which is

J.P.

Perspective view of the Pfalz fuselage stripped of its plywood shell

characterized by the same main features, such as large top plane and small bottom plane, one pair of interplane Vee struts on each side, plywood, streamline body, etc. Apart from minor differences in shape, the Pfalz designer has chiefly struck out along original lines in the construction of the body. Whereas in the Albatross one finds the same oval formers connected by longitudinal rails, the manner of applying the three-ply covering is totally different in the two machines. In the Albatross the plywood is put on in small pieces covering only a bay or so; the covering of the Pfalz is in the form of long strips spirally laid on, the strips of the two layers forming an angle with one another.

According to the official report on the tests the following data were established:

**Pfalz Scout, No. G. 141**

Engine	160 hp. Mercedes.
Number of crew	One.
Military duty	Fighter.
Propeller	Axial, Berlin.
Total military load	281 lb.
Climb to 10,000 ft.	In 17 min. 30 sec.
Speed at 10,000 ft.	102½ m.p.h.; rev., 1,400 r.p.m.
Rate of climb	360 ft./min.; rev., 1,310 r.p.m.
Climb to 15,000 ft.	In 41 min. 20 sec.
Speed at 15,000 ft.	91½ m.p.h.; rev., 1,325 r.p.m.
Rate of climb	100 ft./min.; rev., 1,280 r.p.m.
Estimated absolute ceiling	17,000 ft.
Greatest height reached	15,000 ft. in 41 min. 20 sec.

The total military load is made up as follows:

Pilot	Lb.
Two Spandau guns	180
Dead weight	70
	31
<b>Total</b>	<b>281</b>
Weight per sq. ft.	8.56
Weight per hp.	12.84
Total weight of machine, fully loaded	2,056
Weight of machine, bare, with water	1,580
Military load, less crew	101
Crew, as above	180
Fuel, 21½ imp. gal.	155
Oil, 4 imp. gal.	40
<b>Total</b>	<b>2,056</b>

There are in all eight longerons at the top, one at the bottom, one half-way up on each side and four at what would be the corners in a rectangular section body. These longerons run the whole length of the body, with the exception of the top one, which is terminated just to the rear of the engine, and are attached to the formers as shown in the sketch. The longerons are stop-chamfered so as to leave them solid at the formers, into which they are sunk and secured by a wood screw. The formers themselves are built up of smaller pieces of spruce, lap-jointed and covered each side with a facing of three-ply wood.

Reference has already been made to the fact that wing roots are formed integrally with the body. These roots account for the peculiar shape of formers III and IV. Judging by these formers the cross-sectional area is unduly increased at this point, although this may partly be made up for by the shape of the plywood covering, which merges the lines of the lower plane into the curves of the body. It is, perhaps,

Plan and front elevation of the Pfalz

open to doubt whether or not this elaborate arrangement is worth while. Constructionally it must necessarily entail considerable extra work, and aerodynamically it does not look as neat and efficient as the Albatross way of doing the same thing by frankly letting the bottom plane abut directly on the curved sides of the body.

From the perspective view of the Pfalz body, it will be noticed that some of the formers are sloped in relation to the others. Thus, for instance the former in the neighborhood of the pilot's seat slopes back so as to bring it approximately into line with the rear chassis struts, while rigidity is lent to the front portion of the body by sloping one of the formers carrying the engine bearers until its top meets the top of the next former. In this point also the formers are joined to the front struts carrying the top plane, while one of them serves, at the point of attachment of the bottom corner longeron, to transmit the load from the front chassis struts.

One of the difficulties of monocoque body construction has always been that you cannot bend three-ply sheet over a double curvature. That is to say, in sheet form the three-ply will bend willingly to the curvature of the converging sides of a flat-sided body; but as soon as the sides are no longer flat but have a curvature however slight, three-ply in sheet

Illustrating the method of covering the fuselage with plywood

form cannot be employed. In the Albatross this difficulty is overcome by using small sheets, covering only one bay, and forming, in reality, although it is not noticeable, a series of straight bays. In the Pfalz a different method has been employed. The body covering consists of two layers of three-ply, each less than 1 mm. thick. The plywood is evidently manufactured in sheets, and before applying to the body is cut up into parallel strips of about 3 to 4 in., the width apparently varying considerably throughout the body. The first layer of three-ply is then put on by bending it diagonally around the body, attaching it by tacking to the various longerons, en route, and cutting each narrow strip at the top and bottom longerons, which form the terminals, so to speak, of the three-ply covering, which is thus applied in two halves. The second layer of strips is then laid on top of the first, but at a different angle, to which it is secured by gluing, and finally tacked to the longerons. The inside layer is reinforced, in the front portion of the body, by gluing tapes over the joint between adjoining strips of plywood. This and other details are shown in one of the illustrations. In order to spread a joint in the plywood over as large an area as possible the joint is made, as shown, in a sort of saw tooth or serrated butt joint style. This, in brief, is the fundamental construction of the Pfalz body, and differs considerably from other makes. The weight can scarcely be any greater than the girder type of body, but as regards strength we have no information. As a compromise between sheet three-ply covering and true monocoque construction the Pfalz method would appear to have certain advantages.

(To be continued)

### British Dope Investigation

IT hasn't been all smooth sailing in carrying through the aircraft programs of foreign countries, as is well shown by a recent report of a Select Committee on National Expenditure dealing with the dope situation.

In the early days of the war cellulose acetate was not manufactured in England. The principal sources of supply, apart from Germany, appear to have been the Usines du Rhone, at Lyons, and the Cellonite Company, Basle. Private manufacturers obtained it from either of these two sources,

The wing roots or stubs of the Pfalz

but the War Office do not appear to have obtained it direct from the Usines du Rhone until late in 1915, after which date, however, the product from those works was regarded as superior in quality to that of the Cellonite Company, Basle.

Inquiries were made by the War Office early in 1915 regarding the possibility of manufacturing cellulose acetate in England. After preliminary negotiations with several companies tender forms were issued to three firms in July, 1915, for 100 tons of cellulose acetate to be manufactured in England, the manufacturers to state on their tender form to what extent the ingredients would themselves be manufactured there. Of the three companies invited, the Cellonite Company of Basle alone submitted a tender.

The Cellonite Company of Basle submitted a tender in which they undertook to manufacture in England within six months, but reserved the right to supply up to 50 per cent of the total quantity required from their works in Switzerland.

The Cellonite Company's tender of July, 1915, was accepted by wire on the 19th of July, and negotiations immediately followed for the institution of the required manufacture in England. The representative of the Swiss company, Dr. Camille Dreyfus, at once raised the question of the effect upon the undertaking of possible excess profits taxation, and asked for some assurance that it would not be applied to this new venture. This question was referred by the Contracts Branch, through the Director of Military Aeronautics, to the Finance Branch, and met with an absolute refusal, which was communicated to Dr. Dreyfus. It was finally agreed, however, that the Government would refund the amount expended on plant by the company, up to a maximum equivalent to the excess profits duty actually charged in respect of each year's working during the war.

It appears from the report that as a result of this agreement the company went ahead spending money on plant lavishly, but its product left much to be desired both as to quantity and quality. It enjoyed a virtual monopoly and hence was in position to fix its own price. The agreement with regard to the refund of capital expenditure was cancelled in June last, and now it is proposed by the committee that the Government should take over the entire works of the concern, the British Cellulose Company, that a technical committee be appointed to advise upon the necessary steps for the completion of the factory and its efficient management, and that the Government consider immediately the advisability of securing an alternative source of supply of cellulose acetate.

The report concludes: "A private monopoly in a key industry cannot be instituted at Government expense or with Government assistance without arousing criticism and, if only for this reason, the Supply Branch would have been better advised to have secured the full authorization of the Finance Department at every step in their negotiations."

Illustrating shape of body former and method of securing longeron to it

# Renault Builds Light, Speedy Tanks for French Army

*French 2-man tank, which has a speed of 12 m.p.h. and can turn in its own length. The tank is built in the Renault automobile factory and has a 4-cylinder, 40-hp. engine*

**R**ECENT attacks by the French and British have been preceded by great numbers of two-man tanks. These light tanks have been frequently mentioned in dispatches from the front of late and have proved to be a great success in preparing the way for infantry advances. The tanks shown in the accompanying illustrations are those used by the French and have been an important factor in the late offensive of the allied armies. The tank is the production of the Renault automobile factory, having been designed largely in that institution and incorporating a number of features which are original with this concern. The engine is a Renault 40-hp., four-cylinder design, and the track-laying drive is also a distinctive Renault design.

The driver is located at the front end of the machine and the observer, or gunner, is seated in the center or stands upright within the turret. The driver and the gunner both look through slits cut in the armor plate of which the body work is composed, and the turret is mounted on ball bearings, enabling the machine gun carried within it to be pointed in any direction around the entire circle.

The engine is in the rear of the tank, and propels the vehicle through a clutch and a transmission gearing; then to a transverse shaft through two steering clutches, finally to an outbound reduction gearing, and then to the sprocket which drives the track. The track differs materially from that used on the former tanks and is also considerably different from that used on the caterpillar tractors of this country. The track is driven by a sprocket gear at the rear end and passes over a blank gear, or idler, at the forward end. The adjustment of

the track is maintained by the position of this idler, which governs the center distance from the center of the sprocket to the center of the idler. The tension is also maintained by a roller track frame which is forced upward against the inside of the upper links by means of a coil spring.

The body of the tank is hung between two track frames. The track frames are inverted U-beams containing the track drive mechanism. The body is suspended at the rear by means of the drive axle, which passes transversely through it and holds

the sprockets on either side, and is also supported by large coil springs on the brackets which connect the body to the track frame at the forward end.

This tank is capable of a forward speed of about 12 m.p.h., and has four forward speeds and one reverse. It can be whirled about in its own length by holding one of the tracks stationary, while the other propels it

*The engine is at the rear, the track differs materially from the usual type and the turret is mounted on ball bearings, enabling the machine gun to be pointed in any direction*

*In cases of emergency the tank is loaded on a trailer and hauled to the threatened point. Its weight of 6 tons enables this to be done with ease. The armor plate is sufficiently thick to withstand machine gun or rifle fire*

around the stationary track as it pivots. The release and engagement of the tracks is controlled by means of steering clutches which are interposed between the transmission and the spur gear reduction which drives the sprockets.

The tanks are fitted with a tail piece on the rear end which permits them to go up inclines almost vertical without tilting over backward. They can negotiate very rough ground and are comparatively light for this sort of service. The weight of the Renault tank is about

6 tons. It is built throughout of armor plate sufficiently heavy to withstand machine gun or ordinary rifle fire. The ability of these tanks to wipe out machine gun nests and in some cases even capture light field artillery pieces has been greatly responsible for the success of recent French attacks. The Whippet type of tank, which has been mentioned frequently in dispatches of late and is even credited with having chased a brigadier-general from his headquarters, is no doubt an English type corresponding very closely to this Renault design.

## Women Industrial Workers in France

THE French have not, as the British have, established training courses and factories in which women are prepared to take up skilled work. At the outset, says Mary Conyngton in a report printed in the *Monthly Labor Review* of the U. S. Department of Labor, they were trained, as far as any training was needed for what they did, by the men with whom they worked. Later on, when it was desired to put women to work demanding a little more skill, the same method was adopted as in England at the beginning of the war—a group of women were put on machine work, a man being told off to supervise, to keep the machines in order, to adjust and repair tools, and generally to do what the women were not capable of doing themselves. In other cases a woman would be set to work as a helper to a man; sometimes she would be assigned to him as a kind of apprentice, being expected to pick up his work as rapidly as possible.

In March, 1917, the minister of armaments addressed a circular to the directors of artillery establishments, pointing out the need of training more workers for skilled operations and giving details of a plan for offering this training. Women, especially those who were young and had shown aptitude for the work, were to be included in this training. Even before this, occasional references had appeared in different ministerial circulars to women employed in work demanding both skill and training. Presumably these have been trained by individual employers for work in their own shops.

The necessity for intense production has led to the installation of automatic machinery and subdivision of labor, two conditions which are usually favorable to a good production on the part of women. Where strength is a requisite the women are said to be less effective than men, but where dexterity and swiftness count, their output is the better.

A former factory inspector of France, writing of the condition of French working women, says that the system of reductions from their piece rates on account of improved services or masculine help tends to increase their output.

At the lathes for 155-shells the women have been provided with pneumatic tackle, and for this reason get a "quarter" while men have a higher wage because they handle the shells by hand. Yet the women succeeded in turning more shells in a day than the men. The women thus obliged to produce 125 pieces while the workmen produce only 100 force themselves continually. War industry has used women to

speed up production. They have frequently set a new pace in factories where it was insufficient.

Officially France has not, up to a recent period, displayed much interest in the question of how the women engaged in these new occupations may fare at the close of the war. There has been some discussion of the matter by various writers on economic and social problems, in which some anxiety appears as to the effect of their competition in lowering wages, but the main concern has been as to the effect on the race of their economic emancipation. When the great increase in the employment of women began some writers argued strongly against the admission of women to the new and better paid occupations, stating frankly that if a woman can earn living wages there is little chance that she will marry, or, marrying, consent to bear children. The government, however, does not seem to share this fear, for it has lately called on the Committee on Women's Work to investigate and report on the best way of utilizing industrially the women who will be set free as the demand for munitions declines.

The committee, after taking counsel with trade-unionists, women leaders, social workers, and large employers, decided that the first step was to make a survey of the women at present employed, and of the demand likely to exist for their services at the close of the war. They have accordingly sent out to employers a questionnaire, asking each to return full details as to the number of women at present employed, with their industrial history, and also to give an outline of what plans the employer has for his own business after the war, stating how many women he will then wish to employ. The committee also asked for the opinions of those questioned as to the best steps to be taken in order that the "valuable collaboration" which women have given to munition work may be continued to the advantage of peace industries. The results of this investigation are not yet at hand.

ACCORDING to *L'Industrie Electrique*, great difficulty is being experienced in France in getting sufficient platinum for electrical work, and the Société des Experts Chimistes de France has suggested a tax on all luxuries using this metal. Various alloy substitutes are proposed, including gold palladium, which costs about half the price of platinum, and certain nickel chromium and iron silicon alloys.

# The Automobile Outlook in Holland

A Market Not Neglected Previous to the War—Native Industry Practically Non-Existent—Many New Fortunes Created May Lead to Big Demand When Peace Returns

By a Correspondent

**H**OLLAND is a small country with fairly good roads which, as a rule, are very narrow. The country is quite flat and in the greater part of the country the roads are paved with small brick, but in the southeastern part there are a few roads made of concrete.

Previous to the war, every kind of car, whether of English, French, Belgian, Italian, German or Austrian make, was represented in Holland, and practically all American cars too. Even American firms with no reputation in the United States were among those doing business in Holland. As a matter of fact, I do not know a single country in the world where more different makes of cars were represented than in Holland.

In my estimation the annual sales in Holland did not exceed 1,200 cars, and with the exception of a few makes which did a fair business, most of the makers sold from 1 to 6 cars a year in this country; competition, therefore, was very keen, as for one buyer there were at least 20 agents offering 20 makes.

The total number of motor cars in use in Holland is very difficult to get hold of, as the officials to whom I have addressed an inquiry several times do not want to give that information to me (a foreigner). They are evidently afraid that I would take advantage of the information.

I estimate the total number of cars in use in the Netherlands at between 6,000 and 8,000.

Up to the beginning of the war, only the very rich people made use of cars. Large numbers of Dutch people who could afford to buy a motor car did not think that their means allowed them to keep one.

## War Put Stop to Imports

Since the outbreak of the war practically all importation of cars has ceased, although during the early part of the war the Germans did send, now and then, a few German cars to Holland and more recently they shipped a certain number of Belgian, French and even English cars which they had taken in Belgium or in the north of France and which they had put into proper condition in Germany. The Belgian, French and English governments having strongly protested to the Dutch authorities against these importations of stolen cars, such importations have practically ceased.

In the first year of the war, Holland did import a fair number of American cars, including Overlands, Cadillacs, Hupmobiles, Fords, Maxwells, Hudsons, Oldsmobiles and a few Packards and cars of other makes. Shipping difficulties have stopped these importations.

People in Holland who before the war would never have considered owning an American car (considered as a cheap car) have been compelled by the force of circumstances to buy such cars, and no doubt the American car is considered better now than before the war.

The automobile industry in Holland is only in its infancy. There really is only one works in the country manufacturing cars, and that only on a very small scale, namely, the N. V. Nederlandsche Automobielen Vliegtuigfabriek Trompenburg, Amsteldijk, Amsterdam. This company was established several years ago by Spyker

Bros., an old coachbuilding firm. When the motor car industry started they began to build bodies for chassis made by other manufacturers, and later they decided to build a factory for the making of chassis themselves. They started in a small way and at one time were fairly successful, their products being sold throughout Holland and the Dutch East Indies, besides having a small sale in England.

One of the Spyker brothers lost his life a couple of years before the war when the steamer *Berlin*, belonging to the Great Eastern Railway Line, foundered off the mouth of the Hook of Holland Canal. The other brother not being in position to continue the business alone, this was turned into a stock company, and at present Henri Wynmaelen, the old flyer known from the "European Circuit," is managing director of the concern.

## Building Aeroplanes Now

The Trompenburg company is now building aeroplanes for the Dutch government and is also trying to build cars; but under the present conditions this is quite impossible, no material being available in Holland and no importation of same being possible.

The capacity of the Trompenburg works, however, is very limited, and I do not think they can make more than a couple of hundred cars a year if they manufacture the units themselves. I have been told, however, that after the war they expect to build cars from units made for them in the United States.

Besides the Trompenburg factory, there is a small place called "Eysink" in Amersfoort which pretends to be a factory of motor cars but which is no more than a big repairshop. There is not even a first class repairshop in Holland capable of making new parts for modern machines if necessary.

Dutch people, although rich, are very conservative and do not spend their money so readily as people in other countries. They stick to their money and therefore Holland has certainly not had, up to the present moment, the importance it could have had as an automobile market.

It is possible that after the war, when cars can again be produced at low cost, and freight and insurance will be normal again, so that the American car can be sold in Holland at as favorable a price as in the United States, quite a new clientele for motor cars will be found in this country. This hope seems the more justified because a great many people who had no money when the war broke out have become very prosperous and want to spend their money when circumstances allow it.

## Encouraging the Use of Coal Gas

**W**E understand that the offer by the Automobile Association of England of \$5,000 for the best method of using coal gas on motor vehicles has aroused considerable interest. A number of inventions have been definitely entered for competition, and, in addition, many valuable suggestions motorists and others interested have been received by the Association. Incidentally, the competition has stimulated research and investigation concerning the possibility of using other fuels besides coal gas, gasoline and gasoline substitutes.

# Welfare Work in a Rubber Plant

## What Experience Has Demonstrated Regarding the Requirements of Rest Rooms and the Cost of Maintaining Them—A Hotel for Women Workers

A VERY complete system of rest rooms for girls has been maintained by the B. F. Goodrich Company at its plant in Akron, Ohio, for the past four years. A photograph of one of these rooms is reproduced herewith. It is quite evident that the Goodrich company has gone into this matter with characteristic thoroughness. It is also apparent, from the real luxury and good taste displayed in the furnishing of the room illustrated, that the company believes, when it comes to welfare work, that half measures do not pay.

Manufacturers will be interested in the cost of operating such rest rooms, and we are, therefore, giving the figures for the room shown in the photograph as furnished us by the Goodrich company. The following table of costs gives an idea of the maintenance expense on an annual basis:

Dimensions of room .....	20 x 80 ft.
Rental at 43 cents per sq. ft. ....	\$688
Light .....	25
Heat .....	75
Furniture depreciation (original cost \$900) ....	225
Magazines .....	30
Music and victrola records .....	20
Total annual cost .....	\$1,063

Experience justifies an annual depreciation of 25 per cent on the equipment, and it is considered a mistake to economize too stringently in purchasing the requisite material.

According to the Goodrich company, the chief factors to be considered in the construction and maintenance of a girl's rest room are: Good ventilation, light, spaciousness and quietness. A minimum of 12 sq. ft. per person is considered essential.

While there is but one window in the room illustrated, additional light is secured through skylights and, furthermore, the partitions on two sides of the room do not extend to the ceiling. It is generally considered best, wherever possible, to have rest rooms on the outside of the building so that the girls may look out of the windows and rest their eyes by using them for distant observation. Eyestrain from constant close work is a common cause of nervous disorders.

The room illustrated will serve for approximately 300 girls per day. There are, of course in addition, other rooms where cots are provided to permit complete relaxation for those who require it.

The responsibility of supervision over the rest room in the case of the Goodrich company is delegated to certain com-

*From this view of one of the rest rooms maintained at the plant of the B. F. Goodrich Co. it is apparent that the company believes that welfare work well done pays well*

*The Goodrich Co. started its hotel for women employees when the problem of caring for workers who came to the plant from other centers became acute*

*One of the several living rooms each of which is equipped with piano. Visitors are entertained in these rooms*

*One of the double rooms in the Goodrich hotel for women. The charge for a room like this is \$1.50 per week per girl*

petent young women employees who arrange their lunch hours so that they may spend regular lunch time in a supervisory capacity in the rest room. No definite schedule of regulations has been drawn up aside from the general stipulation that in order to retire to the rest room at other than the regular lunch period, it is necessary for a girl to secure the permission of a designated forelady in her department.

The rest rooms in the Goodrich plant are located in the various factory buildings at convenient points.

A group of buildings formerly occupied by a church organization was taken over by the company and converted into something approaching a hotel. One of the buildings was used as a dining room and gymnasium and the other buildings were fitted up as sleeping rooms giving a total of 80 rooms which will accommodate 165 girls.

Girls working at the Goodrich plant may live at this hotel and are charged \$1.50 to \$1.75 each for double rooms and

\$2.25 per week for the single rooms. They are allowed 16 meals per week for \$4.50, these meals including breakfast and evening dinner on the first five days of the week and three meals each on Saturdays and Sundays. The total cost for room and board is, therefore, between \$6 and \$6.75 for each girl and this is said to be much cheaper than accommodations could be obtained anywhere near the plant.

The double rooms, one of which is shown in a photograph herewith, are fitted with twin beds, a dresser, wardrobe, chiffonier and several chairs. A few larger rooms accommodate three girls, but a much greater number are single rooms which are fitted out in a similar manner.

On each floor are ample bath and toilet facilities. In the basement is a completely appointed laundry where the girls may have the use of tubs and electric irons.

The dining room is run on the cafeteria plan and a special point is made to serve only the very best of simple foods.

# Prospects for Tractor Sales in Australia

**I**N the course of time, Australia will prove one of the most attractive fields for the sale of American tractors, in the opinion of Juan Homs, a special agent of the Department of Commerce, who is the author of Bulletin No. 166 of that Department, on Agricultural Implements and Machinery in Australia and New Zealand.

The introduction of farm tractors in Australia has been accompanied by the same vicissitudes that marked the early sale of these machines in the United States and elsewhere. Several years ago, when tractors began to receive marked attention in this country, they were imported into Australia in some numbers. It was found, however, that the purchasers were, as a rule, not prepared or equipped to make a success of their operation. More than to any fault of the machines themselves, their failure must be attributed to the inadequate manner in which they were sold and put in the hands of the purchasers. This was, at least in part, due to the lack of provision made by manufacturers and importers for properly informing the owners with regard to the handling of the machines, and to the inadequate consideration given to the fundamental principles that should have been observed in placing machinery of an unknown type in the hands of the farmers. Most of the machines imported into the Commonwealth during what may be termed the "first period" in the development of the tractor business remain to-day as significant evidence not so much of their unworthiness as of the hasty and ill-advised methods that governed the first attempts to introduce them. This is to be sincerely regretted, for the advent of the smaller, more serviceable, simpler, and better tractor of to-day, with the enormous possibilities that are apparently open to it in Australia, is not so favorably received there on account of the injudicious policy in the past. Notwithstanding the favorable conditions existing in Australia for the tractors made to-day, their popularization will prove relatively difficult. The bitter lesson, learned alike by manufacturers, importers, and users, will not have been in vain, however, if it teaches more progressive, fundamental, and business-like methods in the introduction and sale of tractors such as American factories are turning out at the present time.

## One of the Most Attractive Fields

Time will undoubtedly confirm the opinion of many observers that Australia is one of the most attractive fields for the sale of American tractors. Nearly every condition is present to warrant such expectations. The extensive character of wheat growing is in itself a factor of great importance in this connection, for it can be safely said that more than 80 per cent of the cultivated area of Australia will probably prove economically adapted for their use. The methods of wheat growing in vogue in that country will enable the growers to perform all the necessary operations with one tractor—to the point that horseless farms may become a reality there.

It would be not only useless, but prejudicial and unfair to more progressive manufacturers as well, for any tractor maker to endeavor to market his product in Australia while leaving the entire burden of introduction upon the shoulders of the importer. Such a policy would be extremely harmful, so far as that country is concerned, to the future of the American tractor industry, which has raised such high hopes and holds such bright promise. There is danger that the confidence of the manufacturers in their own machines, based on an intimate knowledge of their construction, may obscure their realization of the fact that their machines at first will be entirely unknown and will constitute a very perplexing problem to foreign importers and users. It is very important, therefore, that they should be warned of this (even though, in certain cases, such caution may not be necessary), and that they should be prepared to instruct their foreign agents carefully during the introductory period. In most cases this will be impracticable unless competent men from the factories

are sent wherever the machines are introduced, to remain for a reasonable length of time, with the object of instructing the agents concerning every phase of the tractors' work, and operation, so as to insure the complete satisfaction of the ultimate buyer. To neglect doing this will prove disastrous to all concerned, and will render futile the hope of building up a permanent, substantial, and growing demand.

In spite of the adverse conditions brought about by the war (chiefly those having to do with the high cost and scarcity of cargo space), a rather large number of small-sized American tractors have been sold in Australia during the past three years. It is felt, however, that the difficulties likely to be met as long as present conditions continue will render inadvisable any great exertions for the time being, but it is to be hoped that as soon as such conditions disappear American manufacturers will look upon the Australian market as one worthy of their very best thought and attention.

## Smaller Sizes Suit Demand Best

Tractors of from 12 to 20 drawbar horsepower will probably prove the most popular and the best adapted to Australian requirements so far as size is concerned, although the country also offers good scope for the sale of a considerable number of larger machines. Quality will generally be a more important consideration, with most buyers, than low price, although it is not unlikely that at first low-priced machines will have a good run. The ultimate results, however, will undoubtedly justify the greater efforts that may be necessary to introduce an improved type of farm machinery, which in the long run has always proved to be preferred by Australian agriculturists. On account of the sandy character of the soil in many of the wheat-growing districts of Australia, machines possessing any special advantages when working upon such soils will probably be in greater demand than those that may prove unsatisfactory under such conditions. There seems to be a tendency in Australia to agree that machines, with tracks will prove more acceptable than round-wheel tractors, but round-wheel machines will not be discriminated against if they prove capable of doing satisfactory work upon light sandy and wet soils. It will be well for American manufacturers to visualize the conditions under which tractors will work when operating machines of the stripper harvester type. Since only the wheat heads are taken off the crop the tractor will be called upon to travel over a heavy growth of straw, which will cause a good deal of slippage unless the wheels are fitted with suitable lugs. Machines that will successfully burn kerosene will also be preferred, although the difference between the cost of kerosene and gasoline in Australia is not so marked as in the United States.

## Best Class of Dealers

It is difficult at this stage to indicate what class of firms in Australia will be best equipped to handle the tractor trade. The firms interested in the sale of agricultural machinery are generally very progressive, and in most cases they may prove quite capable of handling farm tractors. On the other hand, the firms engaged in the sale of motor cars, a good many of which also sell gas engines and other classes of machinery, might prove to be at least as well equipped to take up this business. Owing to the long terms that it will probably be necessary to give in the sale of tractors, the manufacturer should be satisfied concerning the financial resources of any intending agent and importer before giving him the agency. There appears to be every reason to believe that a group of gas-engine and tractor manufacturers could get together and successfully establish branch houses for the sole object of selling this class of goods.

Three or four Australian manufacturers have taken up the construction of farm tractors, and one of them has already succeeded in turning them out in fairly large numbers. One of the few discouraging features in this connection is that a duty of 30 per cent is paid upon imported tractors.

# A Mechanism for Changing Gears Automatically

Relieves the Driver of the Drudgery of Gear Shifting and Prevents Injury to Gear Teeth by Shifting While Clutch Is Imperfectly Released—  
Gears Shifted and Clutch Operated by Engine Power

**A**N interesting design of automatic gearshift has been evolved by Louis Biava of 235 Central Avenue, West Hoboken, N. J. It is adapted for use on passenger cars, motor trucks and similar vehicles, and a model of the device has been applied by Mr. Biava to a Pierce-Arrow truck.

We have had in the past several types of semi-automatic gearshifts in which the operator works a selector and the shifting of gears is effected automatically when he throws out the clutch; also at least one type of automatic gearshift in which the control factor is the torque on the propeller shaft. Mr. Biava's device is similar to the latter in that it is completely automatic, but in its case the controlling factor is the engine speed.

The power required to shift the gears is derived from the engine and is transmitted through a screw shaft *A* which is driven from the engine camshaft and has right and left-hand square screw threads cut upon it at opposite ends, each thread occupying one-half of the effective length of the screw. Upon each end of the screw shaft there is a correspondingly threaded sleeve *B* and the two sleeves are mechanically connected together by a differential gear *C*, comprising bevel gears cut on the adjacent faces of the two threaded sleeves *B*, a ring or spider riding on the outside of the threaded shaft and a set of bevel pinions on same, meshing with the two bevel gears.

## Threaded Shaft Shifts Gears

Ordinarily as the threaded shaft revolves—that is, as long as the engine is running—and there is nothing to hold the sleeves upon it from revolving, these latter turn idly with the shaft. But when one of the sleeves is held from rotating, it is naturally moved along the shaft by the screw threads. This compels the other sleeve, which is oppositely threaded, to turn at twice the speed of the shaft in order that it may move along the shaft at the same speed, and the differential connection between the two shafts permits it to do this. A shifting yoke *E* spans the screw shaft at each end of the sleeves. It acts through the intermediary of two coiled springs *FF* on a sliding bar *G* to which the gear shifter forks *HH* are connected.

Holding one of the threaded sleeves from rotation moves the sleeves and the sliding gear set connected thereto in one direction, and holding the other sleeve of the set moves the gearset in the opposite direction. As in a three speed and reverse gear, there are always two sliding gearsets, two threaded shafts and two sets of sleeves therefor are required.

A description of the means employed for holding one or the other of the threaded sleeves from rotation is next in order.

The element which furnishes the effort required to hold

one of the sleeves from rotating is a centrifugal governor connected to the engine. This governor, shown in one of the illustrations, acts on a cam rod *I*, that is, a rod or bar having a cam groove cut in its surface. In this cam groove is lodged the ball-shaped end of one arm of a bell crank *K*, the other arm of which forms a pawl adapter to engage with ratchet teeth on the threaded sleeve *B*. In certain positions of the cam rod *I*, the pawl is free of the ratchet wheel, while in other positions of the rod it is engaged with the ratchet.

The clutch is automatically released by the gear shifting mechanism, and one advantage of the automatic shift over hand-shifting is that with the former it is absolutely impossible for the clutch to be engaged when the gears are being enmeshed, which sometimes occurs with

Vertical and horizontal sections through gearbox

Details of shifting mechanism

View showing the cam rods

hand shifting and is very destructive of gear teeth. The shifting yokes *E*—which span the threaded sleeves—are provided with cam lobes and form a face cam acting on the clutch lever. When the free end of the clutch lever rests on top of a cam lobe the clutch is released; when it rests in a depression between cam lobes the clutch is engaged, engagement, of course, being effected automatically by the clutch spring. The depressions between cam lobes correspond to the positions of full mesh of the different sets of gears. When the gears are in neutral the free end of the clutch lever is always on top of a cam lobe and the clutch is released.

The same sliding yoke which carries the cams for releasing the clutch also carries a cam—for applying the service brake.

The action of the mechanism is as follows: When the engine is at rest the clutch is disengaged and the gears are in neutral position. By means of the throttle lever on the steering wheel, the gears may be set either for the low speed forward or for the reverse position. This setting is accomplished by the same movement of the lever which partly opens the throttle valve for starting the engine. The throttle lever moves over a semi-circular quadrant which is divided by a stop into two unequal parts. A knob on the lever has to be pulled in order to permit it to pass by this stop. If the lever is at the stop, the throttle valve is virtually closed and the gear is in neutral position. When the lever is moved to the right from the stop, where it has the greatest range of motion, the transmission will be set for first gear forward, and when it is moved to the left of the stop the transmission is set for reverse. The actual meshing of the gears is effected by engine power when the engine is started up.

Supposing the throttle lever to be moved in the direction corresponding to forward motion. As soon as the engine picks up, the low speed set of gears will be shifted into mesh, and as soon as they are fully enmeshed the clutch will be automatically engaged and the car will start off. If the driver wants to continue on first gear for a while, as may sometimes be the case in traffic, all he has to do is to so manipulate his throttle valve that the engine will not run beyond a certain moderate speed. Otherwise, he opens up his throttle and as the engine speeds up the gear shifts automatically to second and finally to third. If the car comes to a hill and the speed in consequence decreases, the gear automatically shifts back to second speed, and, if necessary in order to keep the engine running at a fair speed, to first gear.

On the other hand, if the driver wants to drive slowly on high gear, he will, of course, close his throttle valve. This causes the engine to slow down and the governor

balls tend to approach their axis of rotation and in consequence shift the gears from third to second and finally to first. To prevent this a foot button is provided which when pressed upon, through the intermediary of a linkage *L* and a spring *M*, exerts pressure on the governor sleeve opposite in direction to that of the regular governor spring, keeping the governor balls separated and the gear in high or in second as desired.

In describing this system we have only touched upon its principal features and not gone into all of the details. The system undoubtedly offers some important advantages, such as eliminating the need of manual gear shifting and preventing injury to gears by shifting while the clutch is still engaged. Whether these advantages are sufficient to warrant the complication which it involves cannot be decided offhand. At first one is likely to be prejudiced against any piece of complicated mechanism, but it must be remembered that when properly standardized and made in large numbers such mechanisms may not only be produced quite cheaply but at the same time may be very reliable. Undoubtedly a number of points would require further development, and one condition of operation that does not seem to have received sufficient consideration is when descending a long hill and using the engine as a brake, with a low gear in mesh, when in spite of heavy throttling, the engine might conceivably attain sufficient speed to change to second and third speed. This problem, however, could readily be solved.

Showing governor and method of rendering it ineffective

# Repair Truck Generating Unit

Machine Shop on U. S. Artillery Repair Truck Operated by  
Independent Motors Supplied by Generator—More  
Efficient Than Using Truck Engine

**A**N interesting installation for generating electric power is used on the artillery repair trucks built for the Ordnance Department by the American Car & Foundry Co., in Berwick, Pa. The artillery repair truck is fitted with a lathe, drill press, air compressor set and a number of other machines, each operated by an independent electric motor. In order to supply the current for these independent motors there is a generator set operated by a four-cylinder four-cycle gasoline engine direct connected to a dynamo. This is made by the Universal Motor Co., Oshkosh, Wis.

A set of this kind is compact enough to be mounted upon the body of this repair truck and at the same time supplies sufficient electrical energy (4 kw.) to operate the machines and to give an adequate lighting system for the trucks. It is an easy step from the supplying of current for purposes of this kind to similar purposes on the farm or at any point where a central electric supply system can be utilized. The entire set is so compact that it takes up but a few square feet of floor space. The gasoline tank, radiator engine, and dynamo are so compactly mounted that they are readily carried upon one cast base, which could be placed on any firm foundation and supply current enough to take care of the average farm.

## Self-Contained Unit

The entire unit is self-contained and comprises an engine direct connected to a generator. The armature of the generator acts as the flywheel of the engine. In connection with these two main components there is a radiator and a 5 gal. gasoline tank with the necessary piping. There is also a switchboard which can be mounted at any convenient point.

Since the generator is direct connected, the speed of the armature is the same as that of the crankshaft and the engine governor acts as a regulator. This governor is a throttle type and can be set to any required speed. The normal speed of this particular engine is 1100 r.p.m., at which speed the engine develops 8 hp.

The engine is a four-cylinder unit with the cylinder block cast. It has a bore and stroke of 2½ by 4 in. The manifolds are cast integrally with the cylinders and the cylinder head is detachable. Gray iron pistons are used, with three piston rings, all of which are above the piston pins. The pistons

*Left side of engine-generator set, showing carburetor and connections, also mounting of radiator and oil pump*

*Radiator end of engine-generator set*

have a clearance of 0.003 in. and below the lowest ring are drilled to furnish an oil return passage for the lubricant scraped off the cylinder walls by the piston rings. The piston pin is hollow, hardened and ground. It operates within a bronze bushing contained in the upper end of the connecting-rod. The connecting-rod is a drop forging of I-beam section. At the lower end it contains a die cast babbitt bearing for the crank pin.

## Steel Drop-Forged Crankshaft

The crankshaft is a steel drop forging 1½ in. in diameter. It is direct connected at one end with the armature of the generator which acts as the flywheel, and at the other extremity it terminates in a squared end to take the starting crank engagement. The crankcase and engine bed are bolted together by flange connections and the bed is so shaped as to support the frame of the generator containing the stationary fields and to provide a substantial base within which the unit can be bolted to any firm foundation.

The radiator is an automobile type with a shield to secure the maximum draft of the fan. It is mounted on a frame bolted to the generator casing. The gasoline tank is supported on a bracket by the crankcase of the engine at the starting crank end.

The oiling system is automatic, oiling being taken care of by a removable plunger oil pump. The plunger is actuated by an eccentric on the camshaft. The suction pipe has a fine gauze cap to prevent dirt working up into the pump, and this is inspected by removing the oil pump. The oil is carried to a sight feed device located over the gear case, where the oil flows over the gears and down to the drip pan below the connecting-rod and then finally into the reservoir below. The splash from the connecting-rods lubricates the interior bear-

ings and a form of piston is used to prevent excessive oil from working into the combustion chamber. The surplus oil is scraped down by the lower ring, flowing back through the holes below the lower ring to the crankcase.

The oil sight feed device is composed of a large glass body so that the working of the oil can be seen at a distance from the units.

Cooling is by thermo-syphon, the flow being upward through the straight water pipe connection between the cylinder head and the top of the radiator.

Gasoline is fed by a gravity from the 5 gal. cylindrical tank mounted on the rear end of the engine. The carburetor is a float feed type, with an auxiliary air valve, and the entire gasoline system is readily accessible for cleaning, since the piping and the tank connections are all exposed.

Ignition is provided by a Bosch high tension magneto on the Government installation, although this ignition may be varied for commercial or industrial purposes. The generator is compound wound. It is of 4-kw. or 4000 watts capacity and operates at 110 volts. Regulation of the current output is secured by means of a governor which is of the centrifugal type mounted in an oil tight casing with an accessible cover. In this location it receives oil automatically from the gear case. The following is a list of the general specifications of the engine-generator set used on the artillery repair trucks:

Type of Engine, Four Cycle  
Number of Cylinders, Four  
Cylinder Diameter, bore, 2½ in.  
Stroke, 4 in.  
Brake hp., 8 at 1100 r.p.m.  
Cylinders Cast, in Block  
Cylinder Material, Gray Iron  
Piston Material, Gray Iron  
Piston Clearance, .003 in.  
Number of Piston Rings, 3 per piston.  
Connecting Rod, I-Beam Forging  
Piston Pin Bushing, Bronze  
Lower Rod Bearing, Die Cast Babbitt  
Crankshaft, Drop Forge Steel

Crankshaft Diameter, 1½ in.  
Crank Pin Diameter, 1½ in.  
Crank Pin Length, 1½ in.  
Cylinder Head, Detachable  
Ignition, Bosch Magneto  
Fuel Feed, Gravity  
Governor, Centrifugal Type  
Lubrication, Circulating Splash  
Cooling, Thermo Syphon  
Gasoline Tank Capacity, 5 gal.  
Generator, Multiple Pole Type  
Voltage, 110  
Winding, Compound  
Voltage, 110  
Capacity, 4 kw.  
Switch Board Size, 14 x 24 in.

## Wages and Hours of Labor

MUCH sound industrial philosophy is to be found in the report of the Railway Wage Commission which has just been printed in full in the monthly review of the Bureau of Labor Statistics. An unusual amount of space is devoted to abstract discussions of fundamentals in industrial relations. This is particularly true of the parts of the report devoted to hours of labor and rate of payment for overtime work. What is said there is of interest to all manufacturers.

"The matter of hours of service," says the report, "is lodged deep in labor's mind. A standard day of reasonably limited length is as much a part of the measure of justice with the workingman as is his rate of wage."

"Slowly and steadily, by force of law somewhat, but also by the voluntary act of the employers, a shorter workday is being put into effect. This tendency will continue, and the shorter day will come to be regarded, not as a means of minimizing the returns which the worker gains, but as a conservator of the human material upon which industry rests. This matter of work time must be submitted to the pragmatic test. Society will come to see that there is a maximum which is beyond the Plimsoll mark of wisdom, and a minimum that makes society in many ways the sufferer. The line of moderation, the medial line, is one that must be proved by experience. The wise employer will look with sympathetic eye to find it, and the wise employee will attempt in good faith to make it manifest. It would be a splendid achievement if we could at this time crystallize the experience of the world into a conclusion concerning the length of the workday that would be of universal application. But this is not possible now for many reasons, not the least of which is an insufficiency of data touching so many and such diverse employments which call for such differing strains upon human nerves and muscles.

## Overtime Rates

"Closely allied to the matter of hours of service is that of extra pay for overtime. In fact, the whole theory of those who speak for labor is that extra pay for overtime is the logical way to force the standard day of reasonable hours, with no work thereafter. In that theory there may or may not be force; but, quite apart from such view, certain it is that in harmony with the broader idea that fair hours of rest and recreation are the laborer's right, the use of those hours in industry may well be obtained only at a wage much above the normal. With overtime as with hours of service, however, the commission believes that the existing rules and conditions of payment should not be disturbed during the period of the war. But at the time when the study of the matter of hours of service is made, that study must sympathetically cover also the broad and kindred field of compensation for the overtime which is necessary in certain classes of service."

UNTIL now the English Government has permitted the payment of fees due in enemy countries in connection with the grant, registration and renewal of patents, designs and trade-marks, and also the payment in Great Britain and allied territory, for the account of enemies, of similar fees. It has now been decided to revoke all licenses for the payment of such fees. The reason for this step is said to have been the general public disapproval of the practice of maintaining relations with the enemy.

# Pierce-Arrow Adopts Dual Valves

In New Series Five Cars, T-Head Cylinders with Detachable Heads and Two Intake and Two Exhaust Valves Per Cylinder Are Used—Hill Climbing and Accelerating Ability Greatly Increased

IN engines having individual cylinders of considerable displacement, the provision of two inlet and two exhaust valves per cylinder tends to give increased output and flexibility of operation. In racing engines and aircraft engines dual valves have been used for many years. They have also come into use on stock passenger cars of the four-cylinder type, the chief object sought being to give these four cylinder cars the same range of high gear operation as six-cylinder machines. Now the Pierce-Arrow Motor Car Co., Buffalo, N. Y., has adopted the dual valve principle in its new six-cylinder model. Under the old system of terminology, the car would have been referred to as a 24-valve design, but the Pierce company prefers the more descriptive term "dual valve six."

In the experience of the Pierce company, the demand of the buying public to-day is for better high gear performance. To meet this demand in their 48 hp. model, the company built various types of six, eight and twelve-cylinder engines, and as a result of these experiments, they are now more than ever convinced that a six-cylinder engine is the preferable type for passenger vehicles. It was found that the greater power developed in some of the newly designed engines, especially at the higher speeds, was due almost entirely to the large size of the valves employed in proportion to the cylinder displacement volume, thus insuring a high volumetric efficiency. In order to obtain as great valve capacity in the

*Inlet side of Pierce-Arrow dual valve engine*

six-cylinder,  $4\frac{1}{2} \times 5\frac{1}{2}$  in. engine with which its 48 hp. model has been equipped, as found in some of these high speed engines, it would have been necessary to use 3 in. valves with  $\frac{3}{8}$  in. lift. With a greater lift, of course, a smaller diameter valve would have sufficed, but it was figured that  $\frac{3}{8}$  in. was the maximum lift which would permit of reasonably quiet valve action. This size of valve, however, is prohibitive

because of the noise due to the heavy springs required to close them promptly and also on account of the tendency of the valve heads to warp out of shape. In standard practice, it is seldom that the clear diameter of valve of more than half the cylinder bore is used. For a  $4\frac{1}{2}$  in. bore cylinder, this gives a  $2\frac{1}{4}$  in. valve which is substantially what the Pierce company has been using on its 48 hp. engine in the past. The conclusion was therefore reached that in order to get the maximum power out of the cylinders, it would be necessary to use double inlet and double exhaust valves. The valves used have a clear diameter of  $1\frac{1}{2}$  in. with a  $\frac{3}{8}$  in. lift, thus giving the same opening area as the single valve of 3 in. diameter with  $\frac{3}{8}$  in. lift.

The T-head cylinder construction, which has been championed by the Pierce company for so many years, is still retained but with dual valves it became necessary to make use of detachable heads. Among other advantages claimed for the dual valve construction, aside from increased output from the same size of cylinder, are very quiet valve action due to the use of light valve springs, increased fuel

*Exhaust side of Pierce-Arrow dual valve engine*

economy and less frequent need for regrinding the valves. There is also said to be a remarkable improvement in the acceleration of the car on opening the throttle, the difference being apparent to the driver familiar with the 48-B-4 model.

The modified three-point support, which has been used by the Pierce company for years, is retained. Camshaft drive is by helical spur gears. Water circulation is effected by a centrifugal pump and engine lubrication by the pressure system, through oil passages drilled in the crankshaft. The oil pump is of the gear type.

A carbureter of the Pierce company's own make is fitted and is of the automatic type. Fuel is fed to the carbureter by the pressure system. Ignition is by a Bosch high-tension magneto with a Westinghouse battery system as a reserve. The two systems are independent and connect to separate sets of spark plugs. The timing of the spark is hand-controlled. The starting and lighting system is of Westinghouse make, comprising a separate generator and starting motor, and working on the 6-volt system. All wiring is on the ground return principle. The battery ignition distributor is mounted on the generator. Engagement of the starter drive is effected magnetically. Exide and the Willard batteries are carried.

From the engine the power is transmitted through a cone clutch to the four-speed and reverse selective sliding gear transmission, which is located amidships. The final drive is by spiral bevel gears, these giving a reduction of 3.53:1. The driving thrust is taken on the springs and the torque reaction on a torque arm. The axle is of the semi-floating type and is of the Pierce company's own make.

Wood wheels are standard equipment and are fitted with Goodrich Silvertown cord tires, 35 x 5 in. all around. The front springs are half elliptic and the rear springs three-quarter elliptic. The car has right hand drive and right hand control. Ball bearings are used in the gearset, ball and roller bearings in the rear axle and roller bearings in the front wheels.

The regular equipment includes a speedometer, shock absorbers, demountable rims, one-man top, clock, curtains, power tire pump and windshield. A choice of about twenty different body types is offered the purchaser. The price of the three-passenger roadster is \$6,400 plus war tax, while the five-passenger and seven-passenger touring cars are priced at \$6,500 plus war tax. All models have a 142-in. wheelbase.

## Market for Gas Engines in Australia

**I**MPORT statistics for the Australian commonwealth show a rather steady demand for gas engines in spite of war conditions. Thus the imports under this heading were valued at \$850,825 in 1912, \$936,427 in 1913, \$897,314 in 1914-15 and \$755,709 in 1915-16. The majority of these engines no doubt were small farm engines.

Referring to these figures in a recent publication of the Department of Commerce, Juan Homs states that no other farm machine has been so consistently in demand in Australia since the war started.

Every implement house and many other firms engaged in the sale of machinery other than agricultural, handle gas engines. In spite of this it is felt that any American manufacturer making the type of engines demanded in Australia will find that country a most promising and profitable field, worthy of his best efforts, if he attempts to specialize in the sale of such machines. The sending of special representatives, and even the establishment of branch houses, can be recommended for his consideration, for along certain lines Australia offers an almost virgin field for the sale of gas engines. It is generally believed, for instance, that several thousand engines to run the internal mechanisms of stripper harvesters and binders could be sold in Australia if adequate efforts were made to acquaint the farmers with the many advantages of these machines for that work. Owing to the extremely varied demand, it would be desirable in that case that a complete line of engines should be represented, and several manufacturers under such circumstances might be able profitably to combine and join their efforts in promoting a business solely concerned in the sale of gas engines.

Vertical and horizontal engines in sizes ranging from 1½ to 15 horsepower are sold, the heaviest demand being for 4 and 6 horsepower machines. Almost every kind of engine manufactured is sold in Australia, and while there seems to be a preference for high-grade machines a good many cheap engines are also sold. In the large sheep stations, for instance, where sometimes dozens of engines are used for pumping purposes, the question of price is often a consideration of moment and in some cases the cheapest engines are imported for that trade, although as more experience is had with them a tendency toward a better product is observed. Engines such as are ordinarily sold to farmers in the United States are in great demand for farm work, and these, on the whole, may be classed as the intermediate type, being medium or moderate priced machines.

The fuels used in gas engines in Australia can be said to be equivalent to those used in the United States. The cost of these in the former country is normally about double that in the latter, while during the past three years it has been about three times higher. The fuels used range from low-test kerosene to high-test gasoline, there being but little crude oil used in Australia in connection with the operation of gas engines.

The large number of engines imported from the United Kingdom indicates that substantial, heavy and well-constructed engines are in great demand, for it is well known that thus far English manufacturers have not taken up the construction of engines to meet the demand for low-priced machines. The demand for some of the better American engines, however, is rapidly increasing, and on the whole it is felt that Australia may be regarded as a very promising field for the sale of American gas engines.

## Double Row Fafnir Bearing

**A** DOUBLE row bearing in standard single row widths has been placed on the market by the Fafnir Bearing Company, New Britain, Conn. It will carry nearly twice the radial load of a single row bearing of the same size and, having an angular contact, it will carry an unusual amount of thrust load in both directions. This new bearing is believed to specially meet present conditions, as it is economical of both stock and labor. No retainer is required, as the balls are in staggered relation to each other. The axis of contact makes an angle of 20° with the plane of the bearing.

We understand that the experts of the Fafnir company invented a bearing of this type some five years ago, and a patent on it was immediately applied for. An interference developed, however, as another application covering substantially the same features had been made two years earlier. The Fafnir Bearing Company has now secured an exclusive license under the Mossig and Sachs patent, issued in 1915. The bearing described and illustrated herewith is to be known under the name of the Dragon type bearing No. 411X.

# England Prepares for

Business To-Day Is in America  
Sellers—Demand for

BY SPECIAL

**J**OHANNESBURG, Aug. 4—In the export market, what have the past 4 years wrought and what is the outlook? Speaking for South Africa, it has seen a great increase in American and Japanese business and now a depletion of stocks that will mean millions to be spent immediately conditions permit. While Africa has been giving her sons to fight on the Western Front she has been reaping a material return such as she has never experienced before. Wealth has come to the Union in so large an amount that it has given the necessary impetus long needed to every industry. War conditions are rapidly building up local manufactures, the farming community has benefited as never before, and our coal and iron trade has now become of first importance; in fact, the whole industrial outlook is changed and must now be reckoned with in any survey of the export field.

TO-DAY THE WHOLE automobile business is in the hands of the American manufacturer, but lack of shipping has handicapped it exceedingly. Time was when men, looking at our limited white population, argued that the sale of cars was being overdone, but now it is admitted that we are but in the infancy of the industry. It is a country of vast distances. Our railways touch only a fraction of the population, the necessity for quick intercommunication has become urgent and so the demand steadily increases. With growing wealth has come the increased demand for the better class of cars, but owing to the lack of freight the demand cannot be met, and to-day there is not an unsold high-class automobile in the whole country. What this really means can best be gaged by the fact that the Hudson Super-six sells at \$3,750 and the Cadillac up to \$5,500.

THE PAST 4 YEARS have also seen many changes in the trade, competition has become keener, old methods have had to give place to new, the firms that formerly led are being rapidly out-distanced and the personnel is almost entirely changed. New men have brought to the selling a vision and outlook that were impossible to the old dealer. For the manufacturer to-day to place his agency without a knowledge of these and other changes and to do so simply on the ground of a firm's financial standing or its successful past is to ignore the factors of vital importance. Change is so constant a feature of life here that the reasons which decided the placing of an agency in the past may have given place to conditions prejudicial to the manufacturers' best interests.

SERVICE IS TO-DAY the watchword of all successful business and nowhere has it been more recognized than in the automobile business of America. It is even of more value to a car's reputation in the export field and frequently it receives but scant attention. Hence arises the necessity for more direct supervision because dealers are frequently averse to carrying the necessary stocks of parts because of the capital involved. In fact the problem is an acute one in a country like South Africa, where the distance of the dealer from his source of supply is so great and where the number of towns with facilities for repairs are so few. More cars have had their reputations ruined on this market through want of attention to this than from any other cause.

# South African Trade

## Hands—Our Trucks Are Poor Kerosene Farm Tractor

CORRESPONDENT

FOR THE FIRST time since the opening of the war British automobile manufacturers are making time to pay attention to this territory. Old connections are being restored or new ones sought and there is every evidence that, so soon as conditions permit, the export market will be cultivated as never before. So far there is no evidence of any real attempt being made to compete in the lower-priced car, but in what is your \$1,000 and upwards class the competition will be very keen indeed. The interest of dealers has been awakened and particularly so in cars such as the Crossley, the Arrol-Johnston and the Vauxhall. Previously neither of them could be said to have had anything but small sales, but now in the general opinion of the trade the first two are expected to pitch the note of British competition, especially the former. In the opinion of the writer, one of the first effects of this competition will be a decided reduction in the ratio of profits obtained by the dealer. Sentiment will undoubtedly play a considerable part in furthering their sale, but, on the other hand, many of the American cars will maintain their hold because of their flexibility, their quick response, their gasoline economy, together with the fact that our numerous hills can be negotiated without frequent change of gears.

ONE IMPORTANT and growing field has been left entirely to the British manufacturer, the light or baby car. It is a growing favorite in the towns as a runabout and, with the woman driver, it is much in demand, its extremely low gasoline consumption making it the most economical for short trips.

IT IS SINGULAR and one cannot account for it, but American motor trucks, above the light truck of 1 ton, have never had any appreciable sale in this country. This is all the more remarkable because, when war and our local rebellion broke out, the country was denuded of trucks by their being handed over to the military. Quite a number of American heavy trucks have been used in the German East African campaign and have given every satisfaction, but still our merchants and contractors seem to prefer to wait the advent of the British motor truck before again buying. In the light truck, of 1 or 1½ tons, there was the beginning of quite a considerable business, when shipping scarcity prevented their import. In this class the Maxwell especially has made a good showing and undoubtedly the future demand will be large.

GREAT INTEREST is being shown by agriculturists in the light kerosene farm tractor and a few samples have been imported, but the general verdict is that considerable improvements must be made before they are suitable for the work in South Africa. Our farmers look to them for the breaking of new ground, but so hard is the virgin soil here that, with one exception, none of them has come successfully through the test. Experts also seem to agree that the slow-revolution engine is better suited to our conditions and that the minimum of power must be about 30 hp. With our vast acreage still untilled, and with the increase in the number of our enlightened farmers, together with the high prices ruling for all farm products, few countries offer a better field for a suitable farm tractor.

# Some Outstanding Problems in Aeronautics\*

## Part II

### Engine Problems—Carbureters, Ignition and Lubrication—Variation of Power Output, Lift and Drift with Altitude

By Dr. W. F. Durand

WITH the problem of fuel, that of the prime mover, or engine, is closely related. Is the present type of engine to continue, or is it only a passing stage on the way to some more perfect form? This is a question, interesting indeed for speculation, but hardly to be considered in comparison with actual present moment problems. The present engine and its application to the propulsion of the aeroplane does, furthermore, present no lack of interesting and important problems, and among these a few of the more pressing may here be noted.

First, the problem of gross power. How much power can we put in an aeroplane or airship of no matter what type or form? This divides immediately into three subsidiary problems, as follows:

- (1) How much power from a single cylinder?
- (2) How many cylinders for a single engine?
- (3) How many engines for a single airship?

In the way of power per cylinder we are now reaching close about 40 hp. as a maximum.

In the way of cylinders per engine we have reached a stage of development where the 12-cylinder engine is quite a standard type and higher numbers such as 16 and 18 represent only questions of detail. It is not too much to say that the 600-hp. engine is quite within the reach of present practice and may be realized as called for. We have long since become accustomed to two and three engines on a single plane and are now seeing four engines in various recent designs. It is therefore clear that if a power plant of 2500 hp. on a single structure is wanted, it is quite within the scope of present practice to realize and provide such a plant.

And if four engines of 500 or 600 hp. each, there is no reason why the number may not be increased, at least to a point beyond the present apparent need for power on a single structure.

On the other hand, it must be admitted that, having in view the limitations of present practice, the most simple and in fact the only reliable way of extending power is by a multiplication of the number of cylinders rather than by an increase in the size of the latter. The fact that a 2000-hp. equipment would presumably require from 40 to 60 cylinders shows the formidable degree of multiplication of small elements required to realize such a result. The real problem of size or capacity of engine is therefore one of power in a single cylinder. What can be expected in this direction, and in what way shall search be directed?

#### Cooling the Limiting Factor

The present limitation arises largely as a matter of cooling, and it is in this direction that search may well be made for ways and means of effectively increasing the power capacity of a single cylinder in an engine of the aviation type. This is a problem which is distinctly outstanding and well worth our serious attention and study.

Another problem connected with the engine is that of the

carbureter. At the start of aeronautic engineering the carbureter naturally took its initial form and arrangement from the already fairly well developed automobile engine carbureter. This was but natural, since both engines are of the same type and both use the same general form of fuel. In respect of the conditions of operation, however, there is a marked and important difference. The automobile operates at or near a fixed level and hence in an atmospheric medium of sensibly fixed pressure and density. With the aeroplane the case is very different. The latter may change its level by thousands of feet in a few minutes or even seconds, as in vertical or nearly vertical dives, rapid spirals, etc. This difference in the conditions of operation introduces a factor of distinct significance and of great importance in the design and disposition of the carbureter. Experience in the air has clearly shown the importance of this new factor, and it is not too much to say that the problem of the entirely satisfactory carbureter, capable of automatically answering to the various atmospheric conditions under which it must work, is distinctly an outstanding problem. It is true that much progress has been made and as the result of laboratory research, checked by actual experience in the air, we now know much better than, say two years ago, the fundamental conditions which must be met by the carbureter for the aeronautic engine. The present solution can hardly be considered as final, however, and we may fairly admit that the whole problem of carburetion, including the manifold supply of the carbureted mixture to a multi-cylinder engine, should, as soon as may be, receive a thorough and fundamental re-study in the light of the information to be drawn from the experience of the past three or four years.

#### Ignition

Another problem which we should view as outstanding is that of ignition. It is true that ignition, as now realized with the best equipment, seems to be fairly reliable and effective. But the whole program is open to the objection of requiring an entire electric power plant of a highly specialized type, together with electric conductors and the spark plug for producing the spark between the discharge points within the cylinder. This ensemble, comprising electric generator or magneto, electric cable, distributor for sending the spark with proper timing to the various cylinders and spark plug with discharge points within the cylinder, represents a very complicated and highly specialized device for producing the initial ignition within the body of compressed fuel mixture. In its present state it is a marvel of scientific and technical development, and it does its work; but it is complicated and subject to many possible modes of derangement, and, as we all know, has been and is still the seat of some of the most serious of the engine difficulties to which the power plant as a whole is subject.

I have never been able to persuade myself that this exceedingly complicated and specialized auxiliary equipment was to be the final solution of the problem of producing ignition in an internal combustion engine. If we can anticipate

\*Sixth Wilbur Wright lecture read before the Aeronautical Society of Great Britain at London, June 25.

the explosion engine of the year 1968, assuming that our grandchildren are still dependent on hydrocarbure fuels at that date (and furthermore that they are still available) it would seem as though some more direct and simple mode of initiating the combustion in the cylinders would have been found. Still, otherwise, we may say that on the law of probability, the chances are overwhelmingly against our having at the present moment developed the very best method of ignition. The laws of physics and chemistry, by a probability which almost reaches certainty, contain some potential combination of factors which will permit of eliminating much of the complexity and delicacy of adjustment which is so characteristic a feature of the present mode.

It is perhaps proper to add here that studies in this direction have already been made, and with results which offer promise of interesting developments in the future. The path of perfection is likely to be not a short one, however, and we can see no prospect of any development in the tomorrow of progress likely to displace electric ignition. There must, however, be some better way, and if not to-morrow, then some other morrow should see it made available for use.

The problem of ignition is then one which is distinctly outstanding, one which by its importance merits the most careful study, and one which, at least, offers reasonable ground for hope of a successful and relatively simple substitute for the present mode.

#### Maintenance of Power at Altitude

We come now to a problem of the very highest present and future importance, that of maintaining the power of the engine at high altitude.

The situation as it develops in the case of an aeroplane mounting to higher and higher levels in the atmosphere is readily appreciated with a moment's thought.

The power of the engine arises from the combustion of vaporized hydrocarbon fuel. The power per cycle for a given cylinder will therefore, to a first approximation and assuming a sensibly constant efficiency of thermodynamic transformation, vary directly with the weight of the fuel which can be burned per cycle. But this in turn depends upon and is conditioned by the amount of oxygen which can be drawn into the cylinder per intake stroke of the cycle. But the oxygen is brought in as one of the constituents of the atmosphere and hence the amount of oxygen available per intake stroke will depend upon and be directly proportioned to the amount of air which can be drawn in. But in terms of volume, just a cylinder full or, more exactly, just the volume represented by the piston displacement in moving from one end of the stroke to the other, can be brought in. Hence we may at least depend on what we may term a cylinder volume of air no matter where we are. But just here arises the trouble. The actual weight of air depends conjointly on the volume and on the density, and unfortunately for the aeronautic engine, at least, the density of the atmosphere decreases steadily with altitude, so that at 15,000 feet, for example, the density is only about 60 per cent of the normal density at the earth's surface. It is clear then that an aeronautic engine, other things equal, will draw in, per intake stroke, only about 60 per cent of the weight of air at this altitude as compared with the indraft at the earth's surface. Hence, it will be able to burn only 60 per cent of the fuel and hence with equal efficiency will develop only 60 per cent of the power.

But here we must stop for a moment and inquire as to the effect of such reduction of power on the speed of the aeroplane. We know that, other things equal, the resistance of an aeroplane to propulsion through the air at uniform speed varies directly with the density of the medium. Hence, at the same speed as near the surface of the earth and with the same altitude or angle of attack, the aeroplane at 15,000 ft. elevation would experience only 60 per cent. of the resistance and would hence require only 60 per cent of the thrust, and hence at constant revolutions of the propeller would require only 60 per cent of the power from the engine. Hence, it appears at first sight as though we had lost nothing in speed by the reduction of the power of the engine. If the latter has been reduced to 60 per cent of its amount at low levels, so has the resistance and power required so that the speed realized should remain the same.

Such would, indeed, be the case if this were all of the story; but, unfortunately, other considerations enter and the simple relation of uniform speed at varying altitudes cannot, as a matter of fact, be realized without compensating features.

Thus, if at a constant speed and constant angle of attack for the wings, the resistance to propulsion is only 60 per cent as great at the altitude of 15,000 ft. as on the ground, it is, unfortunately, the same for the lifting force developed by the wings. This also is only 60 per cent as great while the weight of the machine remains sensibly constant at all altitudes. Let us pause long enough to grasp clearly this fact, that while, at constant speed and attitude of flight, the resistance, the lift and all other aerodynamic forces involved vary directly with the density of the air, and hence decrease with the altitude, the weight of the machine, and hence the lift necessary for support, remain sensibly unchanged. Hence, at the same attitude of flight the lifting force at altitude and under the same speed will no longer support the plane, and unless something is done, it would be unable to maintain horizontal flight at such altitude.

Two courses are then open for consideration as follows:

(1) We may seek to increase the speed until at such increased value the lift will equal the weight of the plane. Under the conditions assumed, this would involve an increase of speed of about 30 per cent, thus increasing the resistance to propulsion by nearly 70 per cent or bringing it back to its value at low altitude. But this resistance overcome at the increased speed would mean an increase in the required horsepower of 30 per cent as compared with that normally developed at low level, while with the actual indraft of air and even allowing for the increased speed, only some 78 per cent of this, or 60 per cent of the needful amount would be developed. Hence, no such speed could be realized and the support of the unvarying weight in the rarefied air cannot be realized in this manner, and must be sought otherwise.

(2) Instead of seeking for the necessary lift by increased speed we may seek it by changing the angle of attack; by changing the flying attitude of the plane so that at the same speed, for example, the lifting force will be greatly increased. In this manner the needful lifting force may indeed be realized. But unfortunately with the increase in lifting force will come also an increase in head resistance, not proportionally, but still a definite increase. This will mean that the actual resistance at, say, 15,000 ft. elevation will be greater than 60 per cent of that at low elevation and hence with 60 per cent of the power available per cycle, the original number of revolutions cannot be maintained and a reduction in speed will result. With this reduction in speed will come a further loss in lifting effect and need for a further change in the angle of attack with increased head resistance; until finally, at some reduced speed, a condition will be found where the needful support for the weight of plane may be realized and the resistance to propulsion can be met by the thrust or pull developed at the propeller. Under these conditions, horizontal flight again becomes possible, but at a speed somewhat below that corresponding to low altitude conditions.

#### Loss of Engine and Propeller Efficiency

But this is not all of the story. In addition we must reckon on a diminished efficiency of the engine with decreased power, and with the probability of a loss in propeller efficiency with the resultant change in speed. Thus, if an engine is primarily designed to work at its best efficiency and under its best conditions at or near full atmospheric pressure and density, it will not work with equally good efficiency at high altitudes in rarefied air and when developing only about one-half the power for which it is primarily designed.

All of this means, in brief, then that at an altitude of say 15,000 ft. the plane must fly at a less advantageous angle of attack and hence with more resistance, and that the engine will be able to burn only about 60 per cent as much fuel and will transform the resulting heat less effectively than when at low altitudes. Hence, the power developed will be less than 60 per cent, and hence, insufficient to maintain the same speed; and with diminishing speed there may be further loss of efficiency in the propeller and a further loss of speed until finally matters become adjusted at some value usually definitely and sometimes considerably less than that corresponding to low level conditions.

Hence, as an over-all practical result an aeroplane normally loses horizontal speed as it ascends to higher altitudes.

Confronted with this fundamental fact, what is to be done? Such loss of speed, especially in a military sense, is or may become very serious, and one of the large and definitely outstanding problems in aeronautic engineering at the present time, centers about the possible ways and means of meeting this condition.

The obvious proximate solution is to avoid, so far as may be, the decrease in the amount of air handled per intake stroke of the piston as the plane ascends to higher altitudes.

Broadly, two courses are open. First, we may definitely and frankly design the plane and engine for a certain desired performance at a given altitude, say 15,000 or 20,000 ft. This is a straightforward problem in aeronautic engineering. Given the desired schedule of operation and the altitude, we can determine the resistance to be overcome and the horsepower required, and can design the engine accordingly. In such case the volume of the cylinders will be suited to the rarefied air in which the engine is to work and all proportions and details will be worked out on this basis.

It will be obvious that such an engine will have much too large a piston displacement volume when at low altitude. That is, it will be over size and over powered relative to the plane. In fact, operation near or on the ground under the same adjustments as at altitude would be quite out of the question. Means must therefore be provided for reproducing, when on the ground or at low altitudes, substantially the operating conditions at high altitudes and low air density; that is, the conditions for which the engine was designed. This may be most conveniently done by throttling down the air intake so that while air at or near full sea level density may surround the engine, it will be reduced in pressure at the intake throttle to such a degree that the amount actually taken into the cylinder will only equal that which would normally enter, without throttling, at high altitude.

#### Super Induction

On the other hand, we may definitely design the engine for operation at or near sea level and with size of cylinders and all proportions and adjustments worked out accordingly, and then by a supplementary device endeavor to maintain or to nearly maintain such conditions within the engine itself even if it is at high altitude and surrounded by air of a lower density.

This solution calls for some supplementary form of compressor or equivalent device which shall operate on the rarefied air as a first stage and raise it from the low pressure, characteristic of the altitude, up to or nearly to normal low altitude pressure and density.

Each of these alternatives represents a perfectly solution. Each has its special advantages and disadvantages. Each has its advocates as a solution of this important problem.

The first solution is the simpler of the two, since it involves no special or additional device for compressing the air, however, it means extra weight in the engine which would reduce carrying capacity of the plane.

On the other hand, the compressing device of the second solution is not easy to realize satisfactorily and it involves extra weight, though presumably less than in the first solution. Again, its operation as a separate independent unit for realizing a preliminary compression of the air is less efficient than to do the whole compression by the engine itself and by the engine piston as in the first solution. Only extended and careful trial will presumably be finally decide which is on the whole the better solution.

The reserve necessary with regard to military aviation makes it unwise to attempt to give any account on this question of just where the matter stands with regard to this problem, but it will at least be safe to note that it is a problem which is attracting much attention and study on the part of the various allied Governments, and that much valuable information is being developed, and on which we must wait until some satisfactory solution may be based.

(To be continued)

### The Case Line of Trailers

A COMPLETE line of all-steel semi- and four-wheel trailers has been marketed by the J. M. Case Trailer Co., Racine, Wis. The line consists of models of 3, 4, 6 and 8 ton capacities, and extension pole trailers, and also includes something new in the way of a jacking device.

The pole trailers are built in three sizes, namely, 3, 4 and 6 ton. The latter two are of the extension type when telescoped they give a wheelbase of 9 ft., and when extended, a wheelbase of 16½ ft. For hauling lumber, poles and, in fact, any particularly long material, the pole trailer is the ideal equipment.

One important feature of this line of trailers is that all of the semi-trailers can be instantly converted into a wheel trailer by simply adding the Case front running gear. This front running gear unit is built in various sizes to correspond with the several semi-trailer capacities included in the line. This unit consists of axle, springs, tires, drawbar and steel turntable, upon which rests the front of the semi-trailer, the king pin of the semi-trailer being locked in the center of the turntable. The turntable is equipped with a spring absorber so that the shocks of starting and stopping are taken up.

The company is also furnishing trailer chassis equipped with its own steel dump bodies. These are built entirely of structural steel channels of generous size. The units include Timken roller bearings and Firestone tires, etc.

The new jacking device is of the double-post type and can be operated by one man from either side of the trailer. When not required it is swung up out of the way and is permanently attached to the trailer, it is always ready for use at a moment's notice.

J. M. Case, president, states that motor truck owners are fast realizing the importance of the trailer and that the demand over the country is increasing.

Case 6-ton pole trailer

# Topp-Stewart Four-Wheel Drive Tractor

Principle of Four-Wheel Drive Permits of Light Weight—Tractor Designed for Road Haulage and Road Grading as Well as for Farm Work  
—Engine a Four-Cylinder Waukesha

THE war has brought the four-wheel drive principle to the fore in motor trucks, and Clintonville, Wis., is one of the centers, if not the center, of four-wheel drive activity. Having proven successful in motor truck work, and even essential in the work of the Ordnance Department, it is little wonder that the principle has been applied also in tractor construction. The advantage of the four-wheel drive is that all of the weight of the tractor, as well as that of the driver, is available for traction purposes. The weight of the tractor being equally divided between the four wheels, the tractor will not pack the soil as hard as would one having the bulk of the weight on its two drives. Simpler and less wasteful traction devices can evidently be used than where only about two-thirds of the weight is available for traction.

Traction is secured by means of loose sliding lugs that grip the ground and automatically clean themselves and the wheel. These are put on without the use of bolts, screws or nuts.

## Designed for Road Grading

The engine of the Topp-Stewart is a Waukesha of 4¼ in. bore and 6¼ in. stroke, rated at 45 hp. It has a Kingston carbureter, an Eisemann magneto and a Perfex radiator. The change gear affords three forward speeds, viz. 1½, 2½ and 5 m.p.h. It appears that the tractor is intended for road work as well as for farm work, as mention is made of an instance where it pulled a heavy load up a steep grade when fitted with solid block tires. Road grading is one of the lines of work for which it is specially designed. The change gear is of the sliding pinion type and operates in oil.

The four-wheel drive naturally complicates the construction, but it is said to be applied here in the simplest possible form. Steering and control are arranged more nearly like on an automobile than on most other tractors.

## Four-Wheel Steer

Ordinarily the Topp-Stewart steers on all four wheels, but it can be quickly changed to steer on two wheels only. A brake is provided acting on the main shaft and therefore retards all four road wheels. A belt pulley is furnished only on tractors intended for farm work. The pulley is 14 in. in diameter by 8 in. width of face and is controlled by a friction clutch. A special design of drawbar is provided which acts as a cushion spring both in starting and stopping. The belt pulley is located directly over the rear axle, between the frame and the rear wheel, on the right hand side of the driver. This is said to make it easy to line the tractor up with the machine to be operated and to tighten the belt.

The Topp-Stewart tractor weighs 6500 lb. and develops a drawbar pull of 4500 lb. on low gear, 4200 lb. on intermediate and 2000 lb. on high gear. Power steer, a power winch and a canopy are extra equipment that can be furnished.

Side view of Topp-Stewart tractor with four-wheel drive

## The Lebbey Searchlight

LEBBY ENGINEERING CO. of Charleston, S. C., which specializes in lighting systems for motor yachts, has developed a new design of searchlight for automobiles. In starting to work on the problem it did not plan to evolve some scheme of lenses to modify the angle of light, but to construct an entirely new lamp to secure certain definite results. The conclusion was reached that the first requisite was to produce a lamp which would throw a uniform beam of light on to the roadbed and limit the amount of glare above the horizontal plane of the lamp.

After a year's work a projecting lens was perfected which projected a uniform driving beam, well defined in outline. When this point was reached the company considered the no-glare problem solved. A test pair of the lamps was put in use, fitted with nitrogen bulbs having the front end frosted to cut off direct rays from the filament.

It was found, however, that there was insufficient light directly in front of the car. In order to secure this essential roadside illumination a plane or flat mirror is located close above the bulb, in a horizontal position, with its reflecting surface facing downward. This plane reflector reverses the angle of all the upwardly projected light from the bulb, turning it downward in a wide angle of distribution near the car. Thus an excellent driving light is secured, together with freedom from annoying glare.

We understand that arrangements are under way for the manufacture of this lamp in headlight and windshield floodlight styles.

## Data Sheets on Silent Chains

WE have received from the Morse Chain Co., Ithaca, N. Y., a copy of a booklet of data sheets containing useful information regarding silent chain drives. The data in the booklet cover such subjects as number of teeth and links, lubricating and venting, sprocket materials, chain widths, chain contacts, chain adjustments, etc.

## The Time Element in Industrial Development

**A**UTOMOBILE development in this country began in 1895, and it took till about 1907 to develop a really practical, dependable vehicle. This statement may possibly be challenged, because conceptions of a "practical vehicle" differ. On the one hand the vehicles of 1895 carried their loads and ran in a fashion, and, on the other, those of 1907 were still far from the condition of faultlessness. But by 1907 the automobile had attained such a degree of practicability that manufacturers felt safe in investing enormous sums in equipment for its large scale production, and the general public, as distinguished from wealthy sportsmen, began to buy machines. The production curve in 1908 and 1909 showed a decided upward bend which reflects these developments.

From 1900 on, at least, development work was quite intensive. Large numbers of inventors and

engineers were active in the field, and capital was quite readily available for what appeared to be meritorious designs, and sometimes, alas, only too readily available for the exploitation of what proved to be absolute failures. On the whole, capital was quite ready to back any likely looking improvement, for the immense possibilities ahead of the automobile industry were apparent to all.

In spite of these favorable conditions it took a round dozen years until a really practical design was evolved. Large were the sums of money that were sunk in fruitless experiment in that period. One is tempted to say "wasted," yet many of the problems could be solved only by trial, and failures were inevitable.

The idea occurs that if development had been spread over a longer period—if the outcome of one experiment had been awaited before another was started upon, the same results could have been achieved at much less cost.

But delay in engineering progress is not tolerated in this strenuous age. As soon as a market develops for any engineering product, competition sets in, and those who lead the way in improvement reap the greatest rewards. In this connection it is interesting to note that the development period of the steam engine was incomparably longer than that of the automobile. In turn the development of aircraft is being forced as no engineering enterprise has ever been forced before. The absolute necessity of quick results fully warrants this procedure, but costly mistakes are an unavoidable accompaniment of such hot-house development.

## Why the Unsprung Weight Should Be Minimized

**T**HE rule that the unsprung weight of an automobile should be reduced to the lowest possible figure is generally recognized. It is, of course, violated by the practice of placing the transmission gear on the rear axle, but we remember that one of the earlier prominent champions of this practice did not deny the sound reasoning behind the rule but justified his construction by the statement that his axle with transmission weighed less than other axles of similar cars without the transmission.

The advantage of small unsprung weight, or, in other words, of a light axle, is that the wheels will "keep the road" better; that is, they will not lose contact with the ground as much as the wheels on a heavy axle. This may not be readily apparent, as the heavier axle would seem to press the tire harder to the ground. However, the tire will leave the ground only when the vehicle is proceeding at considerable speed, and in passing over rigid obstacles a blow will be imparted to the wheels and the axle which is directly proportional to the weight thereof.

The force tending to make the wheels adhere to the road, or follow unevennesses in the road bed, is that due to the weight on the wheel, and the greater the total weight on the wheel in proportion to the unsprung weight, the better the wheel will adhere to the road. The effect is much the same as in a valve

operating cam mechanism. In order to make the cam follower follow the contour of the cam even at high speed, we must make the valve and pushrod light and the spring strong.

In a valve mechanism it is very desirable to keep the follower in contact with the cam because that is the condition of noiseless operation. The chief reason for wanting to keep the drive wheels of an automobile in contact with the ground is that this preserves the tires. When the tires alternately are pressed very hard against the ground and leave the ground entirely, considerable slippage between tire and ground surface is inevitable, and such slippage is, of course, very injurious to the tire.

Aside from large unsprung weight causing abnormal tire wear, it also affects the riding qualities of a car detrimentally. As explained in the foregoing, the upward thrust on the wheel when striking an obstruction is proportional to the unsprung weight. A part of this thrust is transmitted to the car body through the springs, and makes itself felt in the form of an unpleasant jolt. The greater the unsprung weight, the severer the jolt.

## Specialized Manufacture of Tractor Axles

THE tractor front axle offers an excellent opportunity for a firm in the drop forging business to establish itself in the tractor parts industry. It is hardly necessary to say that this budding industry has a very promising future, and those who enter it early have a chance to secure a firm footing without much competition.

The front axle is one of the few parts of a tractor that are really ripe for specialized production. It should be made in a drop forging, and very few firms producing tractors have sufficient financial backing to enable them to install the relatively expensive equipment required to make such heavy forgings. In fact, the output of the great majority of plants is not sufficient to warrant the installation of the heavy drop hammers, trimming presses, etc.

While there are great differences in the present designs of tractor front axles, that is mainly due to the fact that the different designers had no acknowledged standard to guide them. A great majority of the present tractors have Ackerman steering, with the axle pivoted to the frame at the center. If an axle is offered the tractor designer that has provisions for a swivel support at the center and for fastening radius rods close to the axle heads, he can easily arrange his frame to fit it.

Only a few—probably not more than three—sizes of axles would be required to meet the whole range of tractor requirements. Of course, the three-plow tractor affords by far the best chances for the parts manufacturer, as it is that intermediate size which suits the requirements of a large number of farms and will be concentrated on by a majority of manufacturers or assemblers. An axle for this size of tractor, therefore, would be the best to start out with.

With what eagerness the manufacturers of tractors go in for parts of specialized manufacture that are of sound design and construction is shown by the heavy demands on engine, clutch and transmission manufacturers from the tractor industry. Moreover, the tractor industry is an essential industry—so recognized by the Government—and any effective work toward the improvement of tractors counts toward the winning of the war.

## Heels

WERE we gifted with a poetic pen we should write an ode or some other accepted form of verse to the wearer of bloomer overalls and French-heeled shoes. We should ask her not to do it. We should appeal to her on aesthetic grounds. We should tell her that dressed in such a combination she is not so handsome as she might be. We should tell her to wear her French heels, if she will, when she dresses herself in petticoats, but not when she slips on bloomers.

Under the circumstances, however, we shall have to say our say in prose and trust that it may be made effective by adding an appeal to reason.

Besides being something horrible to look upon, the French-heel-bloomer-overall combination is only a half measure from the point of view of accident prevention, and therefore needs further consideration on the ground of safety. This fact is recognized by the New York State Industrial Commission, which has prescribed that women operatives in industrial plants shall wear, besides other things, "shoes with low heels."

It is bad enough to have a large part of our women-folk go tottering through social life on semi-stilts at all angles of inclination, but when we permit these potential accident breeders to become an added industrial hazard we are doing something in which there is no reason.

Encourage the woman operative to wear good square heels, and with her bloomers she will not only retain the attractiveness which is her right, but she will also become a better risk for industrial accident insurance.

## England's Dope Scandal

A SITUATION similar to that in our aircraft industry has been revealed in England by an investigation of the dope industry. There were no manufacturers of cellulose acetate in England at the outbreak of the war, and in view of the urgency of the demand the Government was induced to grant a virtual monopoly to a firm started by a foreign capitalist, and to make terms with it which proved exceedingly onerous later on.

The investigation showed that the business was being conducted wastefully and inefficiently. It is now proposed to place the concern under direct Government control, besides which the creation of new sources of dope supply is considered.

# Owners' Conception of Tractor Instruction Book

**Automotive Industries' Editorial Representative Visits Farmers in Illinois  
and Secures Their Impressions**

**T**HE final test of tractor efficiency must take place upon the farm. The farmer himself must be the ultimate judge. The tractor must meet the individual needs of the farmer who buys it else it is a failure so far as he is concerned. For this reason what the farmer thinks about what the tractor manufacturer and the tractor dealer should do is important to the tractor manufacturer. Here we have the farmer's point of view.

"I think every tractor manufacturer should get out a plain, easily read and comprehensible book about his tractor," says D. W. Rice, who is one of the prominent farmers near Champaign, Ill., and who is a tractor owner. "This book should give complete information about the construction of the tractor and also should have full instructions about its operation. You see, we farmers have to teach ourselves a whole lot about the operation of our machines because we cannot be running to the dealer every time some little thing goes wrong. We haven't the time and we can't afford it. We ought to be able to make the ordinary repairs and adjustments ourselves that may be necessary, and this most of us could do if we knew the 'innards' of our machines, how to get at them and what to do to them when they get out of order. If we could have a book, full of pictures, telling us where every little thing belongs and what it is for and how to fix it when it gets out of kilter, then we would be much better fixed than most of us now are to look after our tractors in the right way."

## **Tractor Manuals Needed**

There are at present no more than two tractor manuals which measure up to the requirements as set forth by Mr. Rice. These both are admirable publications and have contributed materially to the satisfaction the tractors they describe have given. No matter how thorough the instruction may be which the dealer gives to his customer, at the very best it must be elementary and cannot cover all the emergencies which are certain to come up in tractor operation. No matter how perfect a piece of mechanism a tractor may be or to what extent operative troubles have been guarded against by the manufacturer, no one escapes from occasional trouble. For the most part these troubles are trivial, as has been proven by countless responses to calls for assistance, and most of them easily could have been corrected by the farmer himself had he only known how to go about it. This the right kind of a tractor manual would teach him.

To remedy serious troubles, such as breakages and the like, the tractor owner must, of course, look to the dealer. This, however, comes in another branch of service which it devolves upon manufacturer and dealer mutually to provide. But the really annoying things about tractor operation are the inevitable things of a trivial kind which the farmer encounters and which are serious only to the extent that his own ignorance of his machine and of its operation makes them so. Supplied with a manual which is copiously illustrated and which indicates the remedy to be applied in case of common

troubles the farmer is far more likely to derive satisfaction from the use of his tractor than he is when he must interrupt his work and wait for a service man to drive out from town.

How the farmer regards such interruptions is expressed by Charles Rhodes, an Illinois tractor owner, who says: "The farmer uses his tractor for necessary work and its value to him lies in its ability to do that work when it ought to be done. When the tractor is out of commission for any cause, the work must stop and the tractor operator is idle. It isn't the same as having something happen to a horse. A farmer nearly always can change teams and go ahead. But when his tractor balks he is helpless. There's nothing to take its place.

## **Dealer Should Carry Repair Parts**

"Then, too, nothing ever happens when it is standing still and doing nothing. It's only when it's needed and it's in use that things go wrong. It means something then for the farmer to be near a dealer who is prepared to give him prompt service when he needs it, and, above all, a dealer who carries at all times a complete stock of repairs. If something breaks in the midst of the plowing season, for instance, and the farmer must wait and delay his plowing until a spare piece can reach him from the factory the delay may rob him of all the advantage his tractor would otherwise be to him. Every tractor dealer, I think, should carry a stock of repairs sufficient to meet all the probable needs of his customers. If the farmer cannot get repairs for his tractor quickly when he needs them then he would better stick to his horses and be done with it."

This brings out clearly the nature and extent of the service obligation the tractor manufacturer and the tractor dealer jointly owe the farmer when the latter buys a tractor. With tractors becoming more and more numerous on the farms of the country this matter of accessibility to an adequate stock of spares is one of increasing importance. Indeed, it is more than important, it is imperatively necessary. When tractors in actual use were fewer in number it was feasible for the manufacturer, either from the factory itself or from branch houses or centrally located distributing agencies, to meet the service needs for a relatively large territory. With hundreds of tractors now in the place of scores, and with thousands in the place of hundreds, this centralized service system no longer is adequate or even possible.

## **Every Agency a Service Unit**

The obvious solution is to make every dealer agency also a service agency for the territory covered by the dealer. This necessitates not only knowledge of what to do in an emergency on the part of the dealer but the possession of the necessary equipment for giving service, including an adequate stock of spares. Many tractor manufacturers already are making it a condition of their agency contracts that the dealer at all times

shall carry a supply of parts sufficient to meet all the probable requirements of his customers. Obviously the size of the repair stock must bear a certain definite ratio to the number of tractors the dealer has sold or may sell in his territory.

It is not only a matter of good business policy to do this. It is as well meeting one of the recognized demands of the trade. The farmer who buys a tractor expects it, and he has a right to expect it. What Mr. Rhodes says is not alone an individual opinion but may be regarded as typical of the views held by farmers on this service question. How much importance the farmer attaches to the dealer giving this kind of service is shown in a further statement by Mr. Rice, already quoted. He says: "If I were favorably disposed to buy a certain tractor, and would buy it in preference to any other, and the dealer who handled it did not carry repair parts for it, I would forget my preference for the tractor and the dealer and would even buy a tractor regarding which I knew little or nothing from some other dealer, provided the second dealer carried spare parts. I think this is one of the most important things a farmer should consider when he buys a tractor."

### Maker Should Have Farmer's Viewpoint

This brings out clearly the necessity which faces the tractor manufacturer of taking the farmer viewpoint into consideration and making the tractor dealer conform to it. There is nothing theoretical about the needs of the farmer. They are actual and concrete. From the motive which in the first place induces him to buy a tractor at all to the last application he makes of it as a power unit on his farm the practical rules. There are certain things to be done. There are certain ways in which they should be done. There are certain times when they must be done. The farmer does not buy a tractor to make experiments with nor because he hopes it will do his work better than he has been able to do it in the past. He buys a tractor because he believes it will be a help and an economy to him and that it actually will do his work better.

It is up to the manufacturer and to the dealer to see that it does what it should do. In the first place it is incumbent upon both to see that the tractor which a farmer buys is adapted to the needs of that particular farmer, after which every facility should be at hand for keeping that tractor in a constant state of efficiency. This is what the farmer expects, and this measures the extent of the service the manufacturer and the dealer must give. As the man to whom the farmer will look directly for service in the future is the dealer from whom he buys, the manufacturer cannot afford to tolerate a single dealer who fails in the ability, the equipment and the disposition to render service.

### Preventing Piston Slap

AN interesting method of preventing side slap of pistons has been devised by A. C. Mason of the Chevrolet Motor Co. Instead of turning the piston cylindrical, as is customary, Mr. Mason turns the skirt of elliptical form. The minor axis of the elliptical cross-section is in line with that of the piston pin, and the major axis is perpendicular thereto. The ring groove flanges and the piston heads are substantially circular in cross-section, and the diameter of this part of the piston is slightly less than the length of the minor axis of the skirt section. The diameters of the ring groove flanges are gradually reduced from the flange nearest the skirt to the head of the piston. It has been found that the skirt of a piston having a major axis equal to 3.685 in. should have a minor axis 0.003 in. to 0.005 in. less in length than the major axis. A very efficient construction is said to be obtained by making the radius of the minor axis 0.002 in. less

in length than the radius of the major axis. A British patent on this construction has been issued to Mr. Mason.

### Cleveland National Spring Head Tool Holder

A NEW tool holder for finishing work has been placed on the market by the Cleveland National Machine Co., Cleveland, Ohio. The holder has been in use at the plant of the manufacturers for over a year, and it is said to have proven absolutely satisfactory. Its principal object is to relieve chatter and give a smooth cut. The tool can be adjusted either way to an angle up to 90 deg. Three tool clamps are provided,

Spring head tool holder

viz., flat  $\frac{1}{8}$  x  $\frac{7}{16}$  in., round  $\frac{3}{16}$  to  $\frac{5}{16}$  in. and square  $\frac{5}{16}$  in. All of the tool clamps are interchangeable, and they can also be inverted so as to throw the tool on either side of the holder. Bits can be used down to  $\frac{1}{8}$  in. in length, and parting tools as thin as 0.014 in. can be used.

The construction of the tool holder with its spring head is obvious from the illustration. The spring has sufficient strength to stand up to all finishing work that would ordinarily be done on a lathe taking a  $\frac{1}{2}$  x 1  $\frac{1}{16}$  in. shank.

### Correction on Traction Hitch Article

MOMENTS were incorrectly taken around the center of the rear axle in the article on tractor hitches which appeared in AUTOMOTIVE INDUSTRIES for June 27 on page 1257. The last paragraph on page 1257 and the first two on page 1258, as well as Fig. 1, are incorrect as the moments should have been taken about the point of contact of the wheel and the ground. The paragraphs in question should read as follows:

Taking moments about the point of contact of the rear wheel and the ground we find, referring to Fig. 1, that the drawbar exerts an unbalanced moment of 1800 ft.-lb. in a clockwise direction. The weight moments through the center of gravity and the front wheels cancel out, leaving a lifting moment of 1800 ft.-lb. on the front wheels counteracted by a weight moment on the front wheels of 4800 ft.-lb.

The total moment tending to keep the front wheels on the ground is thus only 3000 ft.-lb. instead of 4800 and gives a virtual backward shift to the center of gravity of 10.8 in., lessening the load on the front axle by that amount.

Fig. 1—Corrected diagram showing reactions and backward shift of center of gravity from G to G'

## Abandon National Shows During War

**National Automobile Chamber of Commerce Unanimously Votes to Eliminate New York and Chicago Exhibitions—  
New York May Have Truck Exhibit—Local Show Situation Unsettled**

NEW YORK, Sept. 5—The National Automobile Chamber yesterday voted unanimously to abandon the National Automobile Shows during the period of the war. The action was taken at the monthly meeting of the Board of Directors and the reason ascribed is to "further co-operate with the governmental authorities in conserving labor, fuel and transportation."

Thus, for the first time in 18 years, the great national exhibitions of passenger cars and accessories which have drawn the public by tens of thousands to Grand Central Palace in New York and to the Coliseum and the First Regiment Armory in Chicago will not be held.

There is a possibility, however, that New York may see an exhibition of commercial vehicles. For some time the Motor Truck Club of America has been carrying on negotiations for a lease of Madison Square Garden in which to stage a motor truck show. Arrangements have been carried to the point where it is expected that the contract will be signed this week, provided sentiment favors such an exhibition in view of the action of the N. A. C. C. in abandoning passenger car shows for patriotic reasons.

Just what effect the abandonment of the National shows will have on the dealer shows such, for example, as Boston, Kansas City, Minneapolis, etc., is not known and it is a little early to predict. The National Association of Show Managers, representing practically every important local automobile show says:

### Local Shows Unsettled

"It is not possible at this time to state exactly what will happen in regard to the dealer shows although the probability is that there will not be the number held in previous years. Passenger car exhibits are, of course, hardly to be considered; however, there are so many other automotive activities in certain sections, especially in the large agricultural centers that the exhibition situation of next winter can hardly be foretold. One thing is assured, and that is that there will be no shows unless they have the full approval of those who are running the country's industrial war machine."

Local shows have yearly assumed greater importance. The annual Boston show which always has been the great

gathering place for dealers, not alone from New England, but from all over the East, last year drew an attendance of 225,000; last year both Kansas City and Minneapolis staged exhibitions that were easily the most important events of the kind that were held during the year in their respective territories. The Minneapolis show was the greatest automotive exhibition that has ever been held and was larger, both in area and in the number of exhibits than both the New York and Chicago shows together.

The situation with regard to the annual Importers' Salon which is held in the Hotel Astor, New York, is chaotic. It is not unlikely that this, too, will be abandoned.

The action of the N. A. C. C. was not altogether unexpected. Last year the trade wondered whether in view of the war the shows should be put on. This year sentiment against the shows has been augmented by the difficulty of obtaining a place in which to hold the New York exhibit. It has been rumored that Grand Central Palace has been taken over by the government and will be converted into a mammoth hospital. The rumor cannot be confirmed but there seems more than a grain of truth in it.

### First Show in 1900

America's first automobile show was held in Madison Square Garden during the week of Nov. 3, 1900, and was almost immediately followed by the first annual show in Chicago. Surrounding the arena on the main floor of the Garden was an oval track where cars were demonstrated to prove to the skeptical public that they really would run. Rising high above the roof of the Garden was built a plank incline with steep gradient on which the hill-climbing ability of the little steamers of that period was demonstrated. Steam vehicles predominated at that show and for several years thereafter with electric cars occupying second place and gasoline vehicles a bad third. A dozen or more companies whose cars have since become known all over the world were represented at the first show. It was during this first show that the National Association of Automobile Manufacturers was formed.

The second New York show was also held in the Garden in November, 1901,

and held a total of 93 exhibitors—nearly twice as many as the first—and the demonstrating track was omitted. At the 1903 show there were 154 exhibitors, 185 in 1904 and 250 in 1905. This number has grown each year until at the last exhibition, which several years ago outgrew Madison Square Garden, and has been housed in Grand Central Palace, there was a total of 335 exhibitors. Chicago has fully kept pace with the New York show and in the number of exhibits has often excelled it. Its central location has resulted in an enormous attendance of dealers and other representatives of the industry, more than 3000 dealers having attended last year.

Like the New York show, the Chicago show several years outgrew the Coliseum and during the last few years has required this building and the first Regiment Armory as well.

### Statement of the N. A. C. C.

Following is the statement of the National Automobile Chamber of Commerce:

With a view to further co-operating with the governmental authorities in conserving labor, fuel and transportation, the Directors of the National Automobile Chamber of Commerce at their meeting yesterday, unanimously voted voluntarily to recommend to the members the abandonment during the period of the war, of the automobile shows held annually for 18 years in New York and Chicago.

The makers present felt that the holding of automobile shows would be inconsistent with the patriotic obligations of the industry.

At its previous meeting the N. A. C. C. working with the War Industries Board, voluntarily agreed to curtail production of passenger cars to 50 per cent of the production of 1917, and recommended that all automobile companies take on war work as rapidly as it is obtainable.

### Stutz Profits Decrease \$221,912

INDIANAPOLIS, Sept. 4 — Gross profits of the Stutz Motor Car Co. decreased \$221,912 during the 6 months ending June 30, 1918. The total profits were \$424,253 which is equal to \$7.30 a share on 75,000 shares outstanding. This compares with \$8.29 a share for the corresponding period of 1917. Following is the income account as of June 30:

	1918	1917	Decrease
Net Sales.....	\$1,935,957	\$2,489,622	\$553,665
Cost of sales....	1,511,704	1,843,457	331,753
Gross profits....	\$424,253	\$646,165	\$221,912
Selling, administrative and gen. expen.	35,374	50,317	14,943
Balance .....	\$388,879	\$595,848	\$206,969
Int. & dis. earned	9,187	25,927	16,740
Net profit 6 mos	\$398,066	\$621,775	\$223,709

## Treble Tax on Cars; Double Trucks

### New Revenue Bill Also Taxes Accessories Including Tires— Owner's Horsepower Levy

WASHINGTON, Sept. 4—The manufacturer's tax on passenger cars is more than trebled and the tax on motor trucks nearly doubled in the draft of the new War Revenue Bill which has been presented to the House of Representatives by Chairman Claude Kitchin of the Ways and Means Committee. In addition, there is a provision to tax owners of passenger cars on a horsepower basis and a tax of 2 cents a gallon is placed on gasoline.

Under the terms of the new measure, passenger cars are placed in a so-called "luxury list," and, along with such products as candy, cosmetics, chewing gum, etc., are to be taxed 10 per cent on the selling price instead of the 3 per cent which now is assessed. Motor trucks, on the other hand, are to be taxed only 5 per cent. For the first time, a tax has been placed on automobile accessories, including tires and tubes, the amount being 10 per cent. Motorcycles are to be taxed 10 per cent.

It is estimated that these taxes will produce \$123,750,000 and that the horsepower tax to be paid by passenger car owners will produce an additional \$72,920,000. The horsepower tax will be based on the standard method of calculating horsepower by the S.A.E. formula.

Following are the provisions of the new measure which apply particularly to the automobile industry:

#### Accessories Taxed 10 Per Cent

SEC. 900. That there shall be levied, assessed, collected, and paid, in lieu of the taxes imposed by section 600 of the Revenue Act of 1917, upon the following articles sold or leased by the manufacturer, producer or importer, a tax equivalent to the following percentages of the prices for which so sold or leased—

(1) Automobile trucks, automobile wagons, automobile trailers or tractors (including tires, inner tubes, parts, and accessories therefor sold on or in connection therewith or with the sale thereof), 5 per centum;

(2) Other automobiles or motorcycles (including tires, inner tubes, parts, and accessories therefor sold on or in connection therewith or with the sale thereof), 10 per centum;

(3) Tires, inner tubes, parts or accessories, for any of the articles enumerated in subdivision (1) or (2), sold to any person other than a manufacturer or producer of any of the articles enumerated in subdivision (1) or (2), 10 per centum;

SEC. 902. That there shall be levied, as-

essed, collected, and paid upon all gasoline, naphtha, and other similar petroleum products, having a flash point below 100 degrees Fahrenheit, as tested by the Taglibue open cup tester, and suitable for motor power, sold by the manufacturer, refiner, or importer, a tax of 2 cents a wine gallon.

#### Owner's Automobile Tax

SEC. 1006. That sixty days after the passage of this act, and thereafter on July 1 in each year, and also at the time of the purchase of a new or used automobile or motorcycle by a user, if on any other date than July 1, there shall be levied, assessed, collected and paid, upon the use of automobiles and motorcycles, a special excise tax at the rates as follows: Motorcycles, \$5; automobiles (other than electric) of 23 horsepower or less, \$10; more than 23 horsepower and not more than 30 horsepower, \$20; more than 30 horsepower and not more than 40 horsepower, \$30; and more than 40 horsepower, \$50; electric automobiles, \$5 per horse power and 50 cents for each 100 pounds of weight.

In the case of a tax imposed at the time of the purchase of an automobile or motorcycle or any other date than July 1, and in the case of the tax taking effect sixty days after the passage of this act the amount to be paid shall be the same number of twelfths of the amount of the tax as the number of calendar months (including the month of sale or the month in which is included the sixty-first day after the passage of this act, as the case may be) remaining prior to the following July 1.

For the purposes of this section the horsepower of all automobiles other than steam or electric shall be computed as follows: Square the diameter of the cylinder in inches, multiply by the number of cylinders, and divide by two and one-half. In the case of steam or electric automobiles the horsepower for the purposes of this section shall be the horsepower rating fixed and advertised by the manufacturer or importer thereof at the time when sold by him.

#### Canada Takes Control of Steel

MONTREAL, Sept. 5—The Canadian government has taken over the control of steel products in Canada through its War Trade Board. The board will have full authority to direct the extent and character of the steel produced by the various companies but will have nothing whatever to do with the financial or general management of the concerns. The object of the measure is to co-ordinate producing power and insure maximum production.

#### Enlarge "Essential Industry" Group

WASHINGTON, Sept. 5—The 64 original industrial groups which the War Industries Board classed as being essential have been enlarged to 69 groups. It is expected that the list will be completed and ready for publication early next week. The original plan is to be modified so that non-essential industries will be given a place on the preferential list while engaged in war work.

## Gasoline Saving Was 100,000 Barrels

### Fuel Administration Takes Census of Cars Running— Illinois Leads the List

NEW YORK, Sept. 5—It is estimated that between 100,000 and 150,000 bbls. of gasoline were saved in the states east of the Mississippi River by the first motorless Sunday. This is as close as the Fuel Administration can come to the actual figures. These figures were compiled at the instigation of the National Petroleum War Service Committee and reveal that Illinois leads the conservation list through a saving of 95 per cent of the quantity normally used.

In order to obtain the data, a census was taken of all cars passing certain key points between 2 and 4 p. m. on Saturday, Aug. 31, and during the same time on Sunday in the 25 states west of the Mississippi. The difference in the count of cars is taken to represent a fairly accurate figure on the number of cars in use.

It is estimated that the quantity of gasoline that will be saved next Sunday will be still greater when motorists become more familiar with the request of the Fuel Administration and have had a little more time to rearrange their schedule.

Following is the result of the test:

	Sat., Aug. 31	Sun., Sept. 1	P. C. of Reduction	No. of Cars Registered*
Illinois .....	19,997	1,006	95	340,292
Ohio .....	28,774	1,952	93	425,789
Wisconsin .....	2,181	183	90	182,700
Dist. of Columbia .....	7,939	774	90	36,969
Kentucky .....	3,596	891	90	57,543
West Virginia .....	826	107	87	36,400
Louisiana .....	3,269	429	87	38,000
Tennessee .....	10,115	1,265	87	54,000
Indiana .....	2,165	334	85	209,346
Maryland .....	6,400	989	84	63,827
Florida .....	2,282	361	84	43,746
Maine .....	906	149	83	39,538
Massachusetts .....	1,947	354	81	166,384
Alabama .....	3,589	668	81	44,859
Pennsylvania .....	46,923	8,765	81	344,877

## General Staff Holds Truck Control

### Reorganization Order Places Motor Transport Corps Under Army Supervision

WASHINGTON, Aug. 31—That the Motor Transport Corps of the U. S. Army, recently formed as told in a past issue of *AUTOMOTIVE INDUSTRIES*, will remain directly under the supervision and direction of the General Staff is shown by the reorganization of the General Staff with an Operations Division which will contain a Motor Transport Branch to supervise the Motor Transport Corps. This branch will consequently be the supreme body governing purchase, procurement and design of the motor vehicles of the army. The General Staff is the division of the army that plans, develops and executes the army program directly under Secretary of War Newton D. Baker.

This new reorganization apparently means that the Motor Transport Board, comprising officers of the various army corps and bureaus and which is the consulting board working with the Chief of the Motor Transport Corps, will hereafter operate under the direction of the General Staff Branch.

The three directing officers of the Motor Transport Corps are members of the General Staff and since the announcement of the order of reorganization specifically states that no change of personnel is affected, it is expected these officers will form a part of the Motor Transport Branch of the General Staff.

The order which is known as General Order No. 80 also states that the object of the reorganization is to prevent duplication and to correlate the motor activities of the various army bureaus.

It is further stated that in aircraft production, aircraft operations and tank activities will operate directly under the supervision of the Chief of the General Staff in so far as military affairs are concerned.

### Barley Figuring on War Work

KALAMAZOO, Aug. 28—The Barley Motor Car Co. is actively engaged in working out plans to adjust the plant to war work. The company is now figuring on a good portion of Government work. The three-story factory buildings cover 11 acres of ground and have 350,000 sq. ft. of floorspace. The plant is equipped to assemble trucks that do not require unduly large machine tool capacity.

### Signal Corps Loses Aircraft Supplies

WASHINGTON, Aug. 30—The transfer of all aviation and aircraft property now carried by the Signal Corps to the Division of Military Aeronautics and the Bureau of Aircraft Production is ordered by War Department General Orders No. 1. The order authorizes the transfer

of all aircraft supplies consisting of those necessary for the production of airplanes, airplane engines, aircraft equipment, unfinished, unattached or unassembled airplanes, airplane engines or aircraft equipment. These supplies will automatically transfer and become aviation supplies on their delivery to the Department of Military Aeronautics by the Bureau of Aircraft Production.

### Standardize Oil Specifications

WASHINGTON, D. C., Aug. 31—The Specifications Commission of the Allies has arrived in Washington to discuss the standardization of specifications for petroleum products for use by the American Government and the Allies. President Wilson recently announced in a proclamation that standard specifications would be drawn up and appointed an American committee, as was announced in a past issue of *AUTOMOTIVE INDUSTRIES*.

The Specifications Commission from London comprises: W. Fraser, chairman; H. R. J. Conacher, secretary; Engineer Commander A. E. Hyne, Royal Navy; Captain W. E. Guttentag, British Air Ministry; Captain E. C. Paix, French Army; Captain L. Noyer, French Army; Major Galileo, Italian Navy.

The commission met in conference to-day with the American Committee on Standardization of Petroleum Products, composed of the following members: M. L. Regua, general director oil division, U. S. Fuel Administration, chairman; J. W. Williams, secretary; Col. George E. Warren, appointed by Secretary of War; Admiral R. S. Griffin, appointed by Secretary of the Navy; H. L. Doherty, appointed by chairman of Shipping Board; C. B. Young, appointed by Director General of Railroads; C. H. Beal, appointed by Director of Bureau of Mines; Dr. C. W. Waidner, appointed by Director of Bureau of Standards. Further conferences will be held from day to day.

### Tractor Demonstration for Pennsylvania

HARRISBURG, Sept. 3—The State of Pennsylvania will conduct state farm tractor demonstrations on Sept. 19, 20 and 21, when 250 acres for winter wheat will be plowed and cultivated. Plowing is to be done on Sept. 20, when 7 hr. will be given over for this work, from 9 to 12 in the forenoon and 1 to 5 in the afternoon. On the third day, Sept. 21, the tractors will disk, pulverize and sow the wheat. The first day will be very largely given over to getting ready for the work. In these tractor demonstrations it is planned to keep a very complete record of the performance of each tractor, with regard to fuel used, oil required, plowing speed, depth, number of stops, delays, etc.

### Fordsons at Ohio Fair

COLUMBUS, Aug. 31—One of the biggest attractions at the Ohio State Fair, which closed to-day, was an exhibit of 55 Fordson tractors under the charge of E. H. Bryant, distributor for Ohio.

## Purchasing Agents Convene Sept. 23

### Expected That More Than 100 Will Attend 3-Day Meeting—The Program

DETROIT, Aug. 28—Vigorous plans are on foot for the entertainment of the convention of the National Association of Purchasing Agents, which will be held in this city Sept. 23, 24 and 25. It is expected that more than 1000 purchasing agents from all lines of industry will attend this convention, and a big step toward the consolidation of the buying interests of the country will be made on this occasion. The association has already made considerable progress toward the standardization of catalog sizes and is rapidly obtaining the recognition of the largest business interests. During the past year the membership has tripled and is expected to be augmented by the addition of several new branches during the coming fall. The convention headquarters will be the Hotel Pontchartrain. The program of the convention will be as follows:

#### Sept. 23:

- 9.30 A. M.—Meeting of Board of Directors.
- 10.30 A. M.—Convention called to order by E. L. McGrew, President.
- 2.00 P. M.—"How the Purchasing Agent may serve the nation in his work," by C. A. Woodruff, Saxon Motor Car Co., Detroit, Mich.
- "Standardization of printed matter—present and prospective developments," W. L. Chandler, of Dodge Sales and Engineering Corp., Mishawaka, Ind.
- "Trade acceptance from the buyer's viewpoint," H. E. Cass, of Merrell-Soule Co., Syracuse, N. Y.
- 6.30 P. M.—Smoker and entertainment. Dinner and theater party for lady visitors.

#### Sept. 24:

- 9.30 A. M.—"Commercial Bribery—Cause, effect and remedy," W. P. Ogden, of Scovill Manufacturing Co., Waterbury, Conn.
- "Should the stores department be under the Purchasing Agent's control?" Wm. Guggenheim, of Bauer Brothers Co., Springfield, Ohio.
- "Buying substitutes," F. J. Solon, of Owens Bottle Machine Co., Toledo, Ohio.
- 2.00 P. M.—Automobile tour of Detroit followed by visits to manufacturing plants.
- 7.00 P. M.—Annual banquet.
- Sept. 25:
- 10.00 A. M.—Business session. Election and installation of officers. Deciding place of next convention.

### To Speed Up Brass Production

WASHINGTON, Aug. 30—Brass manufacturers met here to-day with the War Industries Board to discuss plans to speed up rolled brass mills production. Plans suggested were:

1—Each mill to take its full share of Government business.

2—Each mill to take work best suited to its equipment.

3—Each mill to cut off all non-essential uses of the products in which there is a shortage.

4—Each manufacturer to get out his product in the face of obstacles to work up to full capacity.

There is a shortage of rolled brass for shells, cartridges, condenser tubes, etc. Labor has been a serious obstacle in the way of increased production. It was stated that with 9600 additional unskilled workers the mills could increase their output 33 1/3 per cent. The gross production of rolled brass now is 2,910,000 lb. per day. Gross demands, according to the listed figures, are 4,685,000 lb. per day. A number of plants are installing additional facilities and will soon increase their output.

#### Would Aid Mineral Production

WASHINGTON, Aug. 31—Stimulation in the production of such metals and minerals as antimony, cobalt, manganese, platinum, tin tungsten and vanadium is provided for in a bill just introduced by Senator Henderson of Nevada, and referred to the Mines Committee. Under its provisions the President would be authorized to requisition and take over any undeveloped or insufficiently developed deposit, mine, smelter or part thereof and to operate under government direction either under a lease or any other agreement. The bill, however, does not affect gold, silver, copper, lead or zinc production or smelters used in their production.

The bill also creates a revolving fund of \$50,000,000 to carry out the purposes of the act. If in the President's judgment such action is necessary, one or more corporations can be established for the purpose of encouraging the production or controlling the distribution of metals. By this provision, Senator Henderson explained, it would be possible for the President to organize a corporation, with the Secretary of the Interior at the head, for the purpose of developing production in western states and another of chairman of War Industries Board as head, which would be in charge of distribution. The bill is a war measure and the powers conferred by it would terminate two years after peace is declared.

#### War Industries Board Creates New Section

WASHINGTON, Aug. 31—The War Industries Board has created a new section to be known as the Facilities Division, which will determine new or additional facilities in any line of production necessary to the conduct of the war, the possibilities of expanding existing facilities, and the best means of creating and locating new facilities. Samuel P. Bush is at the head of the new division and associated with him is D. R. McLennon of Chicago. The Facilities Division will work co-operatively with the Resources and Conversion Section.

## May Pay Over 25% of Government Cost

### President Nullifies Law Limiting Production Payments—Correct Estimating Hard

WASHINGTON, Aug. 31—The President to-day nullified by an executive proclamation the recent action of Congress providing that the Government should not pay an excess of 25 per cent over the cost of production to any manufacturer of raw materials.

An amendment to the army appropriation bill carried the provision which the President has set aside. Congressmen charged that contractors were making excessive profits, but the President states that, "in view of the practical impossibility under existing conditions of making the estimates necessary to comply fully and adequately with said provisions, it appears that the situation is such as to justify a waiver of said provisions," thereby expressing his opinion that it is not possible to forecast in advance of a contract just what the cost will be. The President's proclamation is as follows:

"Whereas, By the Act of Congress, approved July 8, 1918, Public No. 189, 65th Congress, it is provided

"That except as expressly otherwise authorized herein no part of the sums appropriated by this Act shall be expended in the purchase from private manufacturers of any material at a price in excess of 25 per centum more than the cost of manufacturing such material by the Government, or, where such material is not or has not been manufactured by the Government, at a price in excess of 25 per centum more than the estimated cost of manufacture by the Government; provided, that whenever in the opinion of the President the situation is such as to justify such action he may waive the limitations contained in this section:

"And whereas, in view of the practical impossibility under existing conditions of making the estimates necessary to comply fully and adequately with said provisions, it appears that the situation is such as to justify a waiver of said provisions,

"It is hereby ordered that during the present national emergency the limitations contained in the above section be and the same are hereby waived.

"WOODROW WILSON.

"The White House, Aug. 29, 1918."

#### Special Italian Export License

WASHINGTON, Aug. 31—Exports to Italy are hereafter forbidden unless an import license is secured from the Italian Government, according to an announcement made to-day by the War Trade Board.

Applications for licenses to import into Italy any commodity of foreign origin must be filed by the Italian purchasers with the Giunta Tecnica Interministeriale, Rome, before the placing of orders abroad.

After licenses to import have been granted by the above body, the orders may be placed abroad. The prospective

importers should advise the prospective exporters in the United States the numbers of such import licenses, in order that the latter may designate such numbers in their applications for licenses to export from the United States.

Import licenses issued by the Giunta Tecnica Interministeriale are valid for only one shipment, even though such shipment covers only part of the commodities originally licensed for import into Italy.

The Giunta Tecnica Interministeriale will cable to the Italian High Commission in Washington the numbers of the import licenses granted, so that such Commission may approve the corresponding applications for export licenses when filed with the War Trade Board.

#### Ford to Turn War Profits to Government

DETROIT, Aug. 31—Henry Ford will turn back to the Government his entire share of profits gained on war work contracted by the Ford Motor Co. This means that hundreds of thousands of dollars will be returned to the Government. Ford does not hold any of the war contracts personally, but the Ford Motor Co. in which he owns over one-half of the capital stock received the Government business and it is only the disposition of his own shares that Ford has reference to. It is not stated whether the other stockholders will follow suit and return their profits also.

The company is working on Liberty engine cylinders, Liberty engines, caissons for Ordnance Department, helmets, tanks, the naval boats known as Eagles, and other work.

None of the contracts having been completed, no profits as yet have been paid. Various contracts are progressing and the Government is paying the bills for costs, as they are rendered from time to time. Profits will be figured at the completion of the work. At that time Ford will turn his portion of such profit into the United States treasury.

These various contracts were taken at the solicitation of the Government at prices fixed by it and which prices include a profit of about 10 per cent more than cost. The price on Liberty engines was fixed by the Government, but the Ford Motor Co. later voluntarily reduced the price something like 18 or 20 per cent and filed supplementary contracts with the Government on the revised figure.

Ford personally was willing to do all of this work without profit, but he was advised that this could not be done without violating the duty of the officers to stockholders, and besides the Government officials preferred that the contracts should carry with them the same terms as those which had already been made with other contractors for the same kind of work.

#### Ford Has 5000 Service Stars

DETROIT, Aug. 31—There are now 5000 stars in the service flag of the Ford Motor Co. Among those who are represented in the flag are 400 repairmen serving in France as a unit.

## Exports to Norway Restricted

### Requests for Licenses to Export Tires and Oil Now Require Definite Guarantee

WASHINGTON, Aug. 31—Applications for licenses to export automobile and motorcycle tires and tubes and oils to Norway which are not controlled by a Norwegian import association, states the War Trade Board, will not be considered unless the prospective importer has given a guarantee certified by the Norwegian Finance Department and further certified by an American consul in Norway who will furnish the importer an identification number.

It is no longer necessary to have a code word with the identification number. The number should be forwarded by the importer to the prospective exporter in the United States and specify on supplemental information sheet X-106, which should be attached to the application for an export license.

Applications for licenses to export automobile and motorcycle tires and tubes and oils which are controlled by a Norwegian import association must be accompanied by a certificate secured by the importer from the association. This certificate must be either issued or confirmed subsequent to May 10, 1918. The identification number of the certificate should be forwarded by the importer in Norway to the exporter in this country and specified on the supplemental information sheet X-106, which must be properly executed and annexed to the application for export license.

In filing an application for a license to ship these commodities the shipment must be consigned to the association which has issued the certificate, and the exporter must state the name of the person or firm in whose favor the imports certificate was issued, as for example:

Consignee	{ Royal Norwegian Automobile Club
Purchaser Abroad	{ (Here state person or firm to whom certificate was issued)
	{ Address of such person or firm

The War Trade Board states that the following import associations in Christiania will accept consignments of the following articles on behalf of the Norwegian importer actually interested:

Royal Norwegian Automobile Club—Automobile tires and tubes, motorcycle tires and tubes.

Norwegian Cycle Tire Importer's Association—Bicycle tires.

Lubricating Oil Merchants' Association—Lubricating oils, lubricating greases.

#### Air Mail Service Successful

WASHINGTON, Sept. 3—The air mail service between Washington, Philadelphia and New York operated during August without any serious delay or

miss. There were 27 flying days during which 108 legs of the journey were made and during this time but two forced landings were made, one with the delay of 7 min. and the other less than 10 min. One forced landing was made within 4 miles of Belmont Park, the end of the

*This is the poster which the Fuel Administration has prepared and which will be distributed all over the country in the gasoline-saving campaign.*

journey, and was caused by a break of the magneto shaft. The other forced landing was caused by a compass fault, obliging the pilot to land to pick up his course when the instrument failed to operate. The total possible miles of flight were 11,961, of which 11,957 were completed.

During the first 10 days of the month army fliers operated the planes and during the last 20 days the routes were handled by civilian fliers of the Post Office Department, following the taking over of the air mail service from the War Department by the Post Office Department. A total of 5879 lb. of mail was carried. A rigid mechanical maintenance service has been inaugurated, and during the last month not one of the 15 planes in the service was laid up for repairs.

#### Big Drop in British Imports

LONDON, ENGLAND, Aug. 15—In the fiscal year ending March 31, 1917, there were imported into Great Britain 440 complete motor cars as compared with 5740 the previous year. There were imported 105 chassis as compared with 330 in the previous year; and 655 complete motorcycles as compared with 750. This at 33 1/3 per cent duty which is imposed on automobiles, motorcycles, accessories and components brings the revenue to \$1,068,645.

## No More Priorities for Refineries

### Present Refining Capacity Considered Ample—Necessary Enlargements Allowed

WASHINGTON, Aug. 31—Priorities for materials to be used in the construction of new oil refineries will not be approved, according to an announcement made to-day by the Fuel Administration. The present refining capacity in the mid-continent oil fields is considered ample. Priorities will be approved for materials to maintain existing facilities and for such additions thereto as are necessary in the national interest.

Reasonable use of gasoline-driven vehicles as a means of necessary transportation where no other means are available is not prohibited by the Sunday driving ban, says the Fuel Administration. The intention is that all mere pleasure riding be eliminated, but that necessary use of the automobile should not be interfered with. The individual is expected to determine conscientiously the difference between "pleasure riding" and "necessary use." The Fuel Administration will not attempt to tabulate Sunday automobile traffic.

That the measure is regarded as a temporary one, likely to be enforced only for a few Sundays, is shown by the following statement by M. L. Requa, Director of the Oil Division of the U. S. Fuel Administration:

"Motorists are requested," said Mr. Requa, "to initiate every means of conservation possible in the handling and use of gasoline and lubricating oils. The useless operation of engines when the car is not in motion must be discontinued. Extreme care must be exercised that gasoline and oil are not spilled; that leaks are not tolerated and evaporation not permitted. The gasoline and lubricating oil user must realize that there is not an inexhaustible supply of crude oil, and he must appreciate the fact that the need for it now exceeds that of any previous time.

"War needs must be first supplied. By conserving through the non-use of motor-driven vehicles for a few Sundays and the exercise of care in the use of gasoline and oil during other days, there probably will be no necessity for more severe control.

"If this program is followed to the extent that the Fuel Administration believes it will be, a few Sundays will effect the desired conservation."

#### Test Chicago-New York Air Mail Service

WASHINGTON, Sept. 3—Air mail service between New York and Chicago will be tested Thursday, Sept. 5, by the Post Office Department, when a Curtiss and a Standard airplane, each carrying mail, will leave Belmont Park at New York at 6 a. m. to arrive at Chicago at 4 p. m. If successful, this will be the first time that a machine has flown between the two cities in 1 day. The route will be called the Woodrow Wilson Air Way. Stops will be made at Lock Haven at 8.30 a. m., Cleveland at noon, and Bryan, Ohio, at 1.30 p. m., for gasoline

and oil. The schedule calls for a speed of 80 m.p.h., which can be easily maintained unless diverse head winds are encountered. The pilots will chart the course for distinguishing landmarks, safe landing places and to discover the mountains and ravines which create air currents.

The return trip will be made on Saturday, Sept. 7, starting from Grant Park, Chicago, at 6 a. m. The total distance is 745 miles. The postage rate will be the same as on the New York-Washington route, 16 cents for the first ounce and 6 cents for every ounce thereafter. If the service is successful it is expected the Post Office Department will install night air travel between the 2 cities next spring when the planes will leave New York City at 9 p. m. with the heavy afternoon mail and arrive in Chicago for the first morning delivery.

The New York-Chicago route, if established, will be the last air route installed by the Post Office Department until the end of the war.

#### Warns Against Use of Agents to Secure Priority Certificates

WASHINGTON, Aug. 31—Manufacturers and the public generally are advised of the uselessness and inadvisability of employing agents to obtain priority certificates or preferential treatment from the War Industries Board in an open letter by Edwin B. Parker, Priority Commissioner of the Board. The letter follows:

#### TO THE PUBLIC:

"The attention of the Priorities Division of the War Industries Board has been called to the fact that certain individuals are offering their services and soliciting employment to present priority applications and procure the issuance of priority certificates, and also to use their alleged influence in having industries accorded preferential treatment.

"The rules and regulations of the Priorities Division are clear, simple, can be readily followed and will be furnished to anyone applying therefor. The employment of agents not only burdens the applicant for priority with a wholly unnecessary expense, but an attempt on the part of such agents to exert personal influence—which it is needless to say they do not possess—may have a tendency to prejudice the applicant's cause.

"EDWIN B. PARKER,  
"Priorities Commissioner."

#### Milwaukee Dealer Convention Sept. 11

MILWAUKEE, Sept. 2—The Milwaukee Automobile Dealers' Association has taken the initiative in the organization of a state association of dealers and garagemen by calling a mass meeting at Milwaukee on Wednesday, Sept. 11, during State Fair week. Invitations have been issued to approximately 1700 members of the trade in Wisconsin to attend a dinner at the Milwaukee Athletic Club, to be followed by an organization session, at which it is hoped to present F. W. Vesper, St. Louis, president of the National Automobile Dealers' Association, and E. E. Peake, Kansas City, executive secretary of the N. A. D. A., as the principal speakers.

## Michigan Now Short 10,000 Men

### Employment Office Unable to Supply This Number—Machinists Most Needed

DETROIT, Aug. 30—The Michigan district of the United States Employment Service estimates the present shortage of labor in this state to be over 10,000 men. The office arrives at this figure by taking into consideration the number of men demanded by the industries and which the office is unable to secure to meet requirements.

The office receives requisitions from industries every week for 10,000 more men than it is possible to supply. Half of this demand is for highly skilled men and the other half is for common labor; there is only a slight shortage of semi-skilled workers. Of skilled workers, 90 per cent of the demand is for all around machinists; the remaining 10 per cent is for tool makers.

The recent announcement of a shortage of 30,000 men prevailing here was rather misleading, according to an official of the government office. The estimate, he believes, was based on an anticipated demand due to the increasing volume of war work rather than on an actual count of present requirements. Owing to the adjustments made in the various industries the actual labor shortage has not developed to such great proportions as anticipated.

#### Detroit Places 4000 Men

The Detroit offices placed a total of 4000 men last week, of which 65 per cent were semi-skilled men and the balance was evenly divided between common and skilled workers. The week previous a total of 3200 men were placed.

When Provost Marshal-General Crowder's recent "work or fight" order was put into effect an increase of 5 to 10 per cent in the number of applications coming in was noted, but this order is not credited for the stimulation, as a steady increase is manifested from month to month. The number of men placed each month is always greater than that of the preceding month. The office is at a loss to know where all the men come from. Of course, a small percentage of this number are "come-backs."

It is believed that the general conditions are having an influence on men, causing them to seek more essential work. The men early foresaw the present situation and voluntarily set about to seek places of employment where they would be less liable to be disturbed by the Government.

For the 6-month period—Jan. 1 to June 30, 1918—the Detroit office placed a total of 12,874 men. Between the months of April and May a very marked jump in the number of applications is recorded. Twenty per cent more business was done during this period than any time previous or since. With the exception of

this period the percentage of increase has been almost uniformly 5 per cent.

#### Steel Inventories Asked

WASHINGTON, Sept. 3—A nationwide inventory of stocks of steel on hand is being made by the War Industries Board in co-operation with the Department of Commerce to ascertain the supply of steel. The deficiency of production of steel for direct and indirect war needs is the cause of the inventory. More than 40,000 manufacturers have been asked by questionnaires to report the stocks of steel. The present estimated total production of steel is 17,000,000 tons and war demands total over 23,000,000 tons and are constantly increasing.

A number of industries, says the statement issued by the War Industries Board, such as the automobile industry, have been called upon to report stocks of steel on hand so that the War Industries Board could be guided in making an intelligent administration of the steel stocks, but the Board decided that it was necessary to gather complete information from all steel-using industries determined on a general inventory from all manufacturers.

#### Aircraft Bureau Needs Men

WASHINGTON, Sept. 3—An urgent need for accountants and manufacturing cost clerks who have had either office or factory experience, is made public by the Bureau of Aircraft Production. A limited number of voluntary inductions of men registered under the present draft will be allowed. Induction is open only to men in class 1-A who are classified for limited service or who are in the remediable group, and to men placed in deferred classes on account of dependents. The work will not only be of great service to the Government in the production of airplanes, states the Bureau of Aircraft Production, but it will prove beneficial to the individuals because of the training they will receive. Applicants should communicate with the Personnel Officer, Finance Division, Bureau of Aircraft Production, 119 D Street, N. E., Washington, D. C.

#### Wisconsin Registration Total \$2,049,680

MILWAUKEE, Sept. 2—Wisconsin motorists paid the sum of \$2,049,680 into the coffers of the State of Wisconsin in registration and license fees during the fiscal year ended June 30, 1918, according to the report of the Secretary of State. For the previous period the income was \$834,142. The large gain is due both to the doubling of fees in Jan. 1, 1918, and the vast gain in the number of cars registered. Since the beginning of the present year owners pay an annual fee of \$10, instead of \$5; dealers pay \$25, instead of \$10, and trucks pay a graduated fee according to weight, ranging from \$15 to \$25, instead of the flat fee of \$5 formerly in effect.

**To Produce New Milling Machine**

MILWAUKEE, Sept. 2—Frank M. Davis, formerly president and general manager, and John T. Thompson, formerly vice-president and works manager of the Davis Mfg. Co., Milwaukee, now the gas engine division of the Avery company, Peoria, Ill., have perfected a new type of milling machine in the manufacture of which they will engage at once. Experimental work has been completed and arrangements made for quantity production under contract with the Smith Engineering Works, Milwaukee, until it is found practicable to build and equip a new plant in West Allis, on a site already acquired. The machine will be known as the Davis-Thompson continuous miller. The principal feature of this design, which is entirely new, is that it has two sets of milling cutters and a round table, enabling one machine to do both the rough and finish cutting without removing the work from the table. It is claimed the machine does the work of six ordinary millers. Patents have been granted to Davis and Thompson, who will conduct the business under the name of Davis-Thompson Co.

**Madison Motors Merges With Bull Tractor**

INDIANAPOLIS, Aug. 31—The Madison Motors Corp., which was formed in 1915, has merged with the Bull Tractor Co., Minneapolis. The capital is \$1,500,000 preferred and \$1,200,000 common stock. Cecil Gibson, formerly president and general manager of the Madison Corp., is president of the new company, L. A. Brown is treasurer and John F. Green and Frederick N. Judson, formerly controllers of the Bull Co., are on the board of directors. Mr. Green has just succeeded ex-President Taft on the War Labor Board. The factory of the new company is located at Anderson, Ind. Homer McKee will handle the advertising.

**Reed Foundry on 75 Per Cent War Basis**

KALAMAZOO, Aug. 28—The Reed Foundry & Machine Co., which manufactures the "One Man" tractor, is making steel castings for different branches of the war department, for tanks, ships, hydraulic parts used for piercing shells, iron working lathes to be used in machining and finishing shells. Castings for ditching and dredging machinery are made, and these are sent abroad for trench work. Castings are also made for winches and cranes used in powder plants. Over 75 per cent of the Reed company's foundry work is for Government account.

**Automobile Men in Go-Cart Co.**

STURGIS, MICH., Aug. 31—Several prominent Detroit manufacturers and business men have interested themselves in the newly reorganized Sturgis Steel Go-Cart Co., among whom is Norval A. Hawkins, general sales manager of the Ford Motor Co., who is the directing

**Current News of  
Factories***Notes of New Plants—Old  
Ones Enlarged*

spirit of the new enterprise. The company will continue to make the product for which it was designed with certain allied lines which may be taken on later. The new company will be composed of the following officers and directors: President, Charles B. Tuttle, president of the Tuttle & Clark Co., automobile accessories dealer; vice-president, F. L. Burdick of Sturgis, associated with the go-cart company since its inception; secretary and treasurer, D. L. Seymour of Detroit, stocks and bonds. In addition to the officers the directorate is composed of Norval A. Hawkins and John R. Bodde, vice-president of the Peoples' State Bank, Detroit. Among the stockholders is A. L. McMeans, secretary of Dodge Brothers, Detroit.

**Aluminum Castings Expands for War Work**

CLEVELAND, Aug. 29—For the purpose of expediting war work the Aluminum Castings Co. is greatly enlarging its plant. Work is just being completed on one building, 120 by 260, and two more buildings will be constructed on the adjoining land. One of these buildings, which will be used as a core room, is 140 by 260, and costing \$100,000. The company is also erecting sand bins, 32 ft. high, in a building 150 by 460, at a cost of \$150,000. When the two buildings are completed the Aluminum Castings Co. will have six buildings in a group.

**National Tractor Gets New Plant**

CEDAR RAPIDS, Aug. 31—The National Tractor Co. has just finished a large reinforced concrete, brick and steel addition more than doubling the capacity of the plant. This company is building tractors under the Denning patents. The Chicago offices of the company were recently moved to Cedar Rapids, and an Eastern and export sales office has been opened at 151 Fifth Avenue, New York.

**Victor Screw Works Increases Capital**

The Victor Screw Works, Detroit, has increased its capital stock from \$250,000 to \$500,000.

**Dividends Declared**

At a recent meeting of the directors of the Sewell Cushion Wheel Co., Detroit, a 7 per cent cash dividend was declared on both common and preferred stock, which was paid in July to stockholders of record June 15.

The Jordan Motor Car Co., Cleveland, on Aug. 1 paid an 8.6 per cent dividend to stockholders of the original preferred.

**Stegeman Becomes Parker Motor Truck**

MILWAUKEE, Aug. 31—The Stegeman Motor Car Co., which produces the Stegeman truck, has changed its name to Parker Motor Truck Co. The company states: "The name was changed only after careful consideration. The founder of the company has practically no connection with the present organization at all. It was a name of German origin and we believe that as our soldiers return and tell us of what Germany has stood for the prejudice against everything of German origin will be many times greater than it is now."

**Limousine Top Seeking War Work**

KALAMAZOO, Aug. 29—The Limousine Top Co., which manufactures demountable limousine tops, closed bodies and truck cabs and bodies, is seeking to turn its factory over to government production and is bidding on eight or ten items, such as mess tables, packing cases, ambulance bodies, field hospital equipment, etc. The company recently built a three-story addition to its plant, covering a plot 164 by 66.

**Lane 50 Per Cent on Government Work**

KALAMAZOO, MICH., Aug. 31—The Lane Motor Truck Co. is making fifty complete trucks a month for the Government, and the output will be increased to 100 per month within 60 days. The company expects within that time to be devoting itself 75 per cent to Government work. The trucks are of 1½ tons, 2 tons and 3½ tons capacity.

**More Room for Falls**

MILWAUKEE, WIS., Sept. 2—The Falls Motors Corp., Sheboygan Falls, Wis., has broken ground for another factory addition, 60 x 176 ft., of brick and steel, to provide the additional facilities required to handle its Government contracts for vehicle and aircraft engines.

**Galesburg Plant For Dependable**

GALESBURG, ILL., Aug. 31—The plans have been approved for the factory of the Dependable Truck & Tractor Co. The structure is to be 100 ft. in width and 300 in depth and will be completed about Dec. 1. In the meantime, trucks will be manufactured in the temporary quarters secured here.

**Fire Visits Inner Shoe**

GRAND RAPIDS, MICH., Aug. 31—The plant of the Inner Shoe & Tire Co. was destroyed by fire, the damage being estimated at \$30,000, of which \$7,000 is on the building and \$23,000 on the contents. A new factory will be erected on the same site.

**Capital Increases**

The Van Dorn Electric Tool Co., Cleveland, has taken out a permit for a two-story machinshop addition, 37 by 31.

The Dayton Castings Co., Dayton, Ohio, has increased its capital stock from \$15,000 to \$50,000.

**Owston Made Major**

C. W. Owston, formerly purchasing agent of the McCord Mfg. Co., Detroit, has been promoted from captain in the Ordnance Officers' Reserve Corps to major.

George R. Cullen has been added to the staff of the Bearley-Hamilton Co., advertising agent, Grand Rapids, Mich. He was formerly publicity manager of the Hudson Motor Car Co. and editor of the Triangle and the Hudson Super-Six News-Pictorial.

Glenn A. Sanford, who has been associated with the Jackson Steel Products Co., Jackson, Mich., for some time, has been appointed sales manager of the rim division of that company.

Dwight Davis, for some years assistant to the general manager of the Hyatt Roller Bearing Co., Newark, N. J., assumed the position of assistant to the general manager of the Ever Tight Piston Ring Co., St. Louis, on Sept. 1.

T. P. C. Forbes, for some time a partner of John N. Willys, has been appointed assistant sales manager of the Fulton Motor Truck Co. For the past ten months Mr. Forbes has been general traveling representative with the Fulton Co.

V. Hughes has resigned from the Overland Motor Co. to enter Government service as aeronautical engineer, Aviation Section, Signal Corps, and is assigned to McCook Field, Dayton, Ohio.

W. G. Bell has been appointed Canadian sales manager of the Cleveland Tractor Co., Cleveland. For the past four years he has been assistant sales manager in the Dominion of Canada for the Studebaker Corp.

Thomas A. DeVilbiss, president of the Toledo War Industries Commission, has been appointed sub-regional chairman for the Toledo district.

H. B. Garman has been appointed plant manager of the Detroit plant of the Steel Products Co. He has been associated with the company for a number of years as superintendent of the Detroit factory.

George A. Robson, for 3 years office manager and first assistant to the officials and advertising manager of the Chalmers Motor Co., has resigned. He has formed no other connection, but expects to do so shortly.

Clem Jackson has been promoted from the position of assistant chief engineer to chief engineer of the Erd Motor Co., Saginaw. He was formerly with the Mitchell Motor Co., Racine, and at one time was assistant chief engineer of the Haynes Automobile Co., Kokomo.

E. C. Newcombe has been made a director of the Four-Drive Tractor Co., Big Rapids, Mich., and also vice-president. Two resignations from the directorate are those of George A. Wright

## Men of the Industry

### Changes in Personnel and Position

and Harley Frederick, the latter of whom is expected to remain as manager.

C. B. Meyers has been appointed manager of the sales promotion department of the United States Motor Truck Co., Covington, Ky.

L. F. Miller, formerly of the Mitchell Motors Co., Racine, Wis., has accepted a position with the Anderson Forge & Machine Co., Detroit, as metallurgist.

**Franklin Prices Increased \$450-\$600**

SYRACUSE, Aug. 31—The Franklin Automobile Co. has increased the prices of its cars from \$450 to \$600, effective at once. The new prices follow:

Model	New Price	Old Price
4 and 5 pass. tour.....	\$2,900	\$2,450
2 pass roadster.....	2,850	2,450
Sedan .....	3,350	2,950
Brougham .....	3,300	3,300
Town car .....	4,050	3,450
Limousine .....	4,050	3,450

**Congress of National Safety Council to Deal With Accident Prevention**

CHICAGO, Aug. 31—The seventh annual congress of the National Safety Council, which will convene at the Hotel Statler, St. Louis, from Sept. 16 to 20, will be devoted to all aspects of accident prevention and allied topics in relation to war conditions. A message emphasizing the pressing need for conserving man power will be received from President Wilson, the Hon. Franklin K. Lane will deliver an address on "Safety as an Asset in Winning the War," and Charles M. Schwab, director of the Emergency Fleet Corporation, will speak on "The Democratization of Industry." Other addresses on allied subjects of importance will be given by men of recognized authority.

**Representatives of Parts Manufacturers Co-operate With Dauch**

SANDUSKY, OHIO, Aug. 31—The Dauch Manufacturing Co., builder of the Sandusky tractor, has arranged with the various companies manufacturing standard parts used in the construction of the tractor to co-operate to the limit of their various capacities in speeding up production and insuring a more efficient tractor. Accordingly, one executive from each company has been selected to become a member of the Dauch executive board, where he will give the company the benefit of his specialized experience, and thus help in the development of co-operative manufacture.

**Kettering to Address Detroit Section**

DETROIT, Aug. 31—C. F. Kettering, president of the Dayton Engineering Laboratories Co. and president of the Society of Automotive Engineers, will address the Detroit Section on the subject of the future of the airplane industry after the war. The meeting will be held on Sept. 20 at the Hotel Pontchartrain, Detroit, at 8 p. m. It is expected that a number of out-of-town people from the airplane industry will be present to hear Mr. Kettering's address.

**Tractor Rally for Milwaukee**

MILWAUKEE, Sept. 4—Final plans for a state-wide tractor rally to be held in Milwaukee during State Fair week, Sept. 9 to 14, were made by the Wisconsin Power Farming Association at a meeting on Tuesday evening, Sept. 3. The association met on Aug. 27 to discuss plans and postponed action for one week in anticipation of a full attendance of members, each of whom is a sales manager, branch manager or distributor of farm tractors in Wisconsin.

The purpose of the rally will be to bring to Milwaukee all dealers and owners of tractors so that they may be informed concerning the service plan being evolved by the association.

**Machine Shop Men Organize for War Work**

DETROIT, Aug. 31—Another step in the organization in the individual industries of District No. 1 of the Michigan war resources committee of the War Industries Board was taken recently, when the machine shop owners of Wayne, Oakland and Monroe counties met in the Detroit Board of Commerce. The purpose of the meeting was to organize machine shop men so that a survey of their facilities can be made. Similar meetings of the stamping and forging and casting manufacturers have been held and it is planned by the district head to organize all individual industries in the same manner with a sub-chairman in charge of each.

**Some Statistics from Ford**

DETROIT, Aug. 31—Slightly more than 3000 workers from the Ford Motor Co. plant have been transferred to the Ford shipbuilding plant to work on the Eagles within the last 3 months. Between 15 and 30 young men are leaving the plant daily to take their places in the ranks of the navy or the army. Very nearly 6000 have left the factory for national service during the past year.

**Oil Storage in France**

WASHINGTON, Aug. 31—Four oil tanks of 55,000-barrel capacity each have been secured by the Quartermaster Corps for shipment to France, where they will be erected for the use of the American Expeditionary Forces. These tanks will give storage for 11,000,000 gal. of oil or gasoline, approximately the requirements for a 2-month period.

# Industrial Review of the Week

## A Summary of Major Developments in Other Fields

### Pig Iron Production Falls— Washington Conference

As was expected, August pig-iron production fell below that of July. It was at a less rate also than the outputs of April, May and June, but was higher than that of any other month since May, 1917. The total was 3,389,585 gross tons, or 109,341 tons a day, against 3,420,988 tons in July, or 110,354 tons a day—a falling off in the daily rate of about 1000 tons.

The meeting of iron and steel manufacturers in New York on Aug. 28 was occupied solely with the labor question and the matter of possible price changes for the last quarter of the year was not touched. Leaders in the industry realize that even the present insufficient rate of production cannot be maintained unless special measures are taken in connection with the new draft. More important still is the maintenance of existing hours and the safeguarding of the industry for the period of the war against such restrictions of output as have commonly accompanied union control. Some of the recent Washington decisions of labor issues have evidently not taken into account the grave consequences to the war program which would result from a wide enforcement of such findings in the steel and metal-working trades.

The conference on iron and steel prices between the general steel committee and the War Industries Board is appointed for Sept. 18 at Washington. An all-day meeting of the committee in New York, Sept. 3, will be followed by others at which the requests of various groups of manufacturers for higher prices will be considered.

Representatives of the malleable castings industry at a meeting in New York Aug. 30 adopted prices, making a number of revisions in the existing schedule, and these will be recommended to the War Industries Board.

The threatened inventory of the country's stocks of finished steel has been ordered by the War Industries Board. Manufacturing consumers of rolled iron and steel must report what they have down to the smallest holdings. Commandeering of surplus stocks for war purposes is a probable next step.—*Iron Age*.

### Edge May Re-enter British Trade

LONDON, ENGLAND, Aug. 20—S. F. Edge, who was one of the pioneer automobile dealers in England, and who had the sole selling rights of the Napier, will, in all probability re-enter the automobile field. When he sold the Napier for \$1,000,000 one of the conditions was that he should not engage in the automobile industry directly or indirectly for a period of 10 years. That period will soon expire and it is expected that Mr. Edge

and several other manufacturers will develop a line of low-priced automobiles. Nothing is definitely announced yet as to the type of car that will be built.

### California Oil Production Decreases

SAN FRANCISCO, Sept. 5—The production of crude oil in California fields decreased 1037 barrels a day during July as compared with June. During July the total production was 87,737,629 barrels, which averages 281,859 barrels a day. There were 54 wells completed in July with an initial output of 12,022 barrels daily, compared with 46 wells finished in June with an initial daily output of 5492 barrels. Stocks of crude on hand Aug. 1 were about 200,000 barrels in excess of the quantity on hand July 1.

### England Has 3780 Fordsons

LONDON, ENG., Aug. 13—According to a report made in the House of Commons last week there are 3780 Fordson tractors at the disposal of the Food Production Department. There are also 1700 heavier tractors of the following types at the disposal of government departments as follows: Titan, Mogul, Saunderson, Overtime and Clayton. In all some 3780 Fordson tractors are proposed to be used for the department's own tractor scheme, as a large number, if not the majority of these tractors, have been transferred to Henry Ford & Sons for distribution through regular trade channels.

### To Curb Rent Profiteering

WASHINGTON, Sept. 4—To curb rent profiteering in war manufacturing localities the Department of Labor has introduced a bill in Congress, allowing the President to requisition houses and apartments where the rent is excessive for the duration of the war. In event the landlord is not satisfied with the compensation set by the Government, he is entitled under the terms of the bill to sue the Government.

### 1200 Military Tractors a Month

WASHINGTON, Sept. 4—Production of military tractors is now averaging 1200 per month, according to a statement made here this week by the Acting Secretary of War. He stated further that this production is "not nearly what it should be."

### Shuler Axle Expanding for War Work

DETROIT, Aug. 31—The Shuler Axle Mfg. Co. has increased its capital stock from \$150,000 to \$200,000 to allow for further expansion of its plant to meet government requirements. The company is already on a 95 per cent war basis, indirectly, furnishing axles to manufacturers who have received government orders.

### Bituminous Production Better—A Car Shortage

During the week ended Aug. 24 the production of bituminous coal showed the first improvement in five weeks, due to a slight betterment in the car supply. The output for that week totaled 12,603,000 net tons, and would have been much greater if the car allotment had been regular and the loaded cars had been speeded away from the mines. In fact, the erratic car supply during the month of August was at once the despair of the Federal Fuel Administration—which sees the demand for coal growing larger and larger—and a stumbling block to the operator—who wishes to keep his laboring forces intact and instead finds his men leaving for industries that promise more steady employment.

Anthracite production is not only keeping up, but shows an increase in output for the week ended Aug. 24 with the shipment from the mines of 2,134,000 net tons. The total production of anthracite for the coal year to date is estimated at 41,768,000 net tons, an increase over 1917 of 869,000 net tons.

The Lake trade is active. Under governmental stimulus a larger tonnage is being moved from Ohio and West Virginia to the lower lake ports. Shipments are still behind pre-season estimates, however, and in order to enable the Pittsburgh region to meet its quota coal is being withheld from all nonessential industries in that district, while plants on the preference list which had been receiving only 50 per cent of their requirements are to be still further reduced. There is strong basis for the feeling that the Northwest will be supplied before the close of navigation.—*Coal Age*.

### Reorganization of Motor Transport Corps

WASHINGTON, Sept. 4—The article telling of the organization of the Motor Transport Corps in AUTOMOTIVE INDUSTRIES of Aug. 22 was not the official Government statement. The official publicity telling of the organization of this Corps was not given out until one week following the publication of this fact in AUTOMOTIVE INDUSTRIES. The article published in AUTOMOTIVE INDUSTRIES comprised opinions and information gathered here combined with the history of past military truck activities known publicly prior to this reorganization, and which had been told previously in these columns. Copy of the order organizing the Motor Transport Corps which was reproduced was secured from the office of the Adjutant General. These statements are made at the request of War Department officials who are desirous having the public understand that this article was not the official one.

## Aircraft Production Purchases

WASHINGTON, Aug. 31—Following is a list of contracts placed by the Bureau of Aircraft Production recently:

Wright-Martin Aircraft Corp., New Brunswick, N. J., spares for 150-horsepower type A Hispano-Suiza engine.

Curtiss Aeroplane & Motor Corp., Buffalo, hexagon-head bolts with castellated nuts. Cherry Lumber Co., Cincinnati, 60,000 ft. walnut lumber.

Brown & Harris Lumber Co., Holmesville, Ohio, 50,000 ft. walnut lumber.

West Virginia Aircraft Corp., Wheeling, spares for 500 JN4D training planes: Engine-bed bearers, elevators, rudders, wings, landing gears, etc.

John A. Roebling's Sons Co., Trenton, 240,000 ft. balloon cable.

Pyrene Co., care of H. B. Vandergrift, Continental Hotel, Washington, D. C., 5000 Pyrene fire extinguishers.

Liberty Iron Works, Sacramento, spares for 100 JN4D planes: Elevators, vertical fins, landing gears, rudders, wings, etc.

International Register Co., Chicago, 3500 mechanical interrupter gears.

Dayton-Wright Airplane Co., Dayton, spares for D.H.4 planes: wings, stabilizer braces, front direct-wire fitting with tie rods.

Dayton-Wright Airplane Co., Dayton, parts for D.H.4 planes: wings, right and left ailerons, elevators, rudder, landing gears, etc.

Wright-Martin Aircraft Corp., New Brunswick, spares for Hispano-Suiza motors: Speedometer shaft and bushing assembly, cotter pins, air pump parts, gaskets, nuts, etc.

N. C. L. Engineering Corp., Providence, 50 N. C. L. windlasses, complete.

James Cunningham Son & Co., Rochester, 25 Caquot windlasses.

McKeen Motor Car Co., Omaha, Neb., 25 Burton windlasses.

Cleveland Tractor Co., Cleveland, 10 standard model H Cleveland tractors.

Livingston Radiator & Mfg. Co., New York, 541 Handley-Page type radiators.

Whittaker-Glessner Co., Portsmouth, Ohio, 700 steel drums, 110-gallon capacity.

Chase Metal Works, Waterbury, Conn., seamless copper tubing.

Sheffield By-Products Co., New York, N. Y., 40,000 pounds casein.

N. C. L. Engineering Corps, New York, N. Y., 1 N. C. L. kite balloon windlass.

Gilbert & Barker Mfg. Co., Springfield, 10 tanks of 10,200 gallons' capacity each.

Dobbie Foundry & Machine Co., Niagara Falls, 100 No. 21 single-drum hand-power hoists.

Henry Cheney Hammer Corp., Little Falls, N. Y., 14,400 hammers.

Henry Cheney Hammer Corp., Little Falls, 13,150 hammers.

Collier Supply & Equipment Co., Philadelphia, 43 electrical engineers' chests.

Blaw-Knox Co., Pittsburgh, furnishing and fabricating necessary structural steel and accessory structural material for the construction of 70 hangars.

Belmont Iron Works, Philadelphia, furnishing and fabricating 576 columns (approximately 1500 pounds each).

Whittaker-Glessner Co., Portsmouth, Ohio, 1000 steel drums, 110 gallons' capacity.

## Contracts

Ayer & McKinney, Philadelphia, 30,000 pounds casein.

Standard Aero Corp. of New York, Elizabeth, 30 E-1 advanced planes constructed to mount Gnome motors.

Standard Aero Corp. of New York, Elizabeth, 6 E-1 advanced planes constructed to take LeRhone motors.

Fedders Mfg. Co. (Inc.), Buffalo, 109 radiators complete, with inlet and outlet connections.

Hartsell Walnut Propeller Co., Piqua, 1000 wooden air fans.

Hardman, Peck & Co., New York, N. Y., 500 sets of laminations for Handley-Page propellers.

Parsons Pulp & Lumber Co., Philadelphia, 4,800,000 ft. spruce.

Light Mfg. & Foundry Co., Pittstown, spares for OX5 engine, upper and lower crankcase bearing caps.

Lamb, Finlay & Co., New York City, for services in connection with the handling, paying of duties, and shipping of airplane linens, tapes and balloon cloths, which are being imported from Great Britain for the Bureau of Aircraft Production.

Louisiana Oxygen Co., New Orleans, 500,000 cubic ft. hydrogen gas.

Isaac McLean Sons Co., Dorchester, Boston, 10,000 ft. African mahogany and 25,000 ft. Mexican or Central American mahogany.

Ericsson Mfg. Co., Buffalo, parts for Berling, type D81 magneto (99 items).

Link Tool & Machine Corp., New York, miscellaneous thread gages to be furnished from time to time.

Paul Whitin Mfg. Co., Northbridge, Mass., 25,000 yards cotton airplane fabric.

Wright-Martin Aircraft Corp., New Brunswick, spares for type 3 engine (43 items).

Wright-Martin Aircraft Corp., New Brunswick, spares for type 3 engine (43 items).

Universal Grinding Machine Co., Pittsburgh, 1 No. 2 grinder with C equipment.

Stewart-Hartshorn Co., New York, N. Y., 2000 sets complete streamline tie rods for D.H.4 machines.

Witherow Steel Co., Pittsburgh, 2000 sets complete streamline tie rods for D.H.4 machines.

Eastman Kodak Co., Rochester, 5000 United States Army unit sights.

J. V. Stimson & Co., Owensboro, Ky., 50,000 ft. walnut lumber.

Hoosier Veneer Co., Indianapolis, 500,000 ft. walnut lumber.

Canadian Aeroplane (Ltd.), Toronto, Canada, 12 wings for JN4D Canadian planes.

Disco Mfg. Co., Detroit, 3000 C. C. gun synchronizing generators.

Wireless Improvement Co., New York City, 1,500 S. C. R., 65 sets.

Arthur F. Smith Co., New York, N. Y., labor and material required to change 315 sets of curtains.

Electro Metallurgical Sales Corp., New York City, 1000 tons ferro-silicon.

Electro Metallurgical Sales Corp., New York City, 200 tons ferro-silicon.

Novo Engine Co., Lansing, air compressor outfits.

Wright-Martin Aircraft Corp., New Brunswick, crankcase.

Wright-Martin Aircraft Corp., New Brunswick, engine spares.

Wright-Martin Aircraft Corp., New Brunswick, engine spares.

Wright-Martin Aircraft Corp., New Brunswick, engine spares.

Positipe Co., Cleveland, paper film.

American Optical Co., Southbridge, Mass., 10,000 negative lenses.

Gleason Works, Rochester, generators.

Canadian Aeroplanes (Ltd.), Toronto, spares for JN4D planes.

English & Mersick Co., New Haven, radiators.

Dayton-Wright Airplane Co., Dayton, stabilizer braces.

Dayton-Wright Airplane Co., Dayton, stabilizer braces.

Dayton-Wright Airplane Co., Dayton, connections for gasoline rubber joints.

Dayton-Wright Airplane Co., Dayton, control cables.

Dayton-Wright Airplane Co., Dayton, control cables.

Dayton-Wright Airplane Co., Dayton, control cables.

Dayton-Wright Airplane Co., Dayton, stabilizer braces.

Wright-Martin Aircraft Corp., New Brunswick, engine spares.

Wright-Martin Aircraft Corp., New Brunswick, engine spares.

American Steel & Wire Co., 30 Church Street, New York, wire.

Columbia Steel & Shafting Co., 1145-1146 Munsey Building, Washington, D. C., cold-rolled steel.

Western Block Co., Lockport, N. Y., tackle blocks.

Curtiss Aeroplane & Motor Corp., Buffalo, spares for planes.

John A. Roebling's Sons Co., Trenton, N. J., cable.

Buffalo Aeroplane Corp., Buffalo, propellers.

Springfield Aircraft Corp., Springfield, Mass., spares for planes.

Willis-Overland Co., Toledo, Ohio, engines.

Splitdorf Electrical Co., 98 Warren Street, Newark, magneto parts.

Union Switch & Signal Co., Swissvale, Pa., engines.

Winton Motor Car Co., Cleveland, engines and spares.

Union Switch & Signal Co., Swissvale, Pa., engines.

Eastman Kodak Co., Rochester, cameras.

Aero Supplies Co., 864 East Thirty-ninth Street, Brooklyn, N. Y., goggles.

Dayton-Wright Airplane Co., Dayton, Ohio, spares for planes.

Wright-Martin Aircraft Corp., New Brunswick, N. J., engine spares.

C. L. Willey Co., 2558 South Robey Street, Chicago, Ill., lumber.

Firestone Tire & Rubber Co., 312 Colorado Building, Washington, D. C., balloons.

Thomas Morse Aircraft Corp., Ithaca, spares for planes.

Walden-Worcester (Inc.), Worcester, parts for planes.

Walden-Worcester (Inc.), Worcester, parts for planes.

Lionel Mfg. Co., 48 East Twenty-first Street, New York City, flame-proof keys.

Connecticut Aircraft Co., New Haven, Conn., balloons.

Bosch Magneto Co., 223-225 West Forty-fifth Street, New York City, magnetos and switches.

## Calendar

## ENGINEERING

Nov. 14-15—New York. Society of Naval Architects and Marine Engineers. Twenty-sixth general meeting. Engineering Societies Bldg., 29 West 39th Street.

## ASSOCIATIONS

Oct. 7-12—Milwaukee. American Foundrymen's Assn. and 5 allied organizations. Milwaukee Auditorium.

## SHOWS

Sept. 2-6 — Hartford, Conn. Tractor demonstration (State Fair). Will F. Landon, Secy.

Sept. 2-7—Indianapolis, Indiana. State Fair. Indianapolis Automobile Trade Assn.

Sept. 5—Medina, Orleans Co. Tractor demonstration (State Fair) Food Commission. Calvin J. Huson, Director.

Sept. 8-20—Greely, Weld Co., Colo. Tractor Show. Central Community Fair.

Sept. 9-14—Milwaukee. Milwaukee Automobile Dealers, Inc. Fourth Annual Wisconsin State Fair. Hart J. Ruddle, Mgr.

Sept. 9-14 — Syracuse, N. Y. Tractor demonstration (State Fair). J. Ian Ackerman, Secy.

Sept. 9-15—Madison, Wis. Tractor demonstration (State Fair). O. E. Remy, State Fair Secretary.

Sept. 12-13—Marion, O. Tractor demonstrations, Farm Bureau Associations. M. C. Thomas, County Agricultural Agent.

Sept. 14-21—Chicago. Automotive and Accessories War Exposition. Municipal Pier.

Oct. 14-27—Dallas, Tex., Seventh Annual Texas Automobile Show. Texas State Fair.

Sept. 17-20—Riverhead, L. I. Tractor demonstration (County Fair). Harry Lee, Secy.

Sept. 30-Oct. 4—Trenton, N. J. Tractor demonstration (Trenton Fair). Harry B. Salter, Supt.

Oct. 16-18—Ottawa, Ont., International Plowing Match. Tractor and Farm Machinery Demonstration. Experimental Farm.

Oct. 30-Nov. 4—Shreveport, La. Tractor demonstration. State Fair.

Nov. 11-16—Phoenix, Ariz. Tractor demonstration, State Fair.

## RACING

Sept. 7 — Chicago. Chicago Speedway.  
Sept. 21—Sheepshead Bay.  
Oct. 5 — Cincinnati. Cincinnati Speedway.

Complete with bracket and electric cord

# Stewart V-RAY SEARCHLIGHT

*A Real Searchlight—Not a "Spotlight"*

When you have occasion to use a searchlight, you want a *real* searchlight—not a "spotlight" with its small restricted "spot" of light.

You want a strong, powerful, all-revealing searchlight beam. That is what you have in the Stewart V-Ray Searchlight. Its penetrating shaft of light shoots 'way down the road, revealing even the most distant objects.

The exterior design is particularly noteworthy. See how it stands apart—a thing of beauty. Observe how symmetrical it is. Note the design of the body; also the back.

It is beautifully finished with many coats of jet black enamel, baked on. And there is just a touch of nickel here and there to make the "tailor-made" appearance complete.

The Stewart V-Ray Searchlight harmonizes with the design of the modern automobile. Adds to its appearance. Looks like a built-in part of the car—not like a misplaced, re-vamped headlight.

It is scientifically designed. Made with a perfect parabolic reflector, which is silver-plated—not polished tin. Has a full six inch curved lens, instead of plain window glass.

A 3¼ inch reducing mirror, included at no extra cost, is located in the center of the back. It is not necessary to twist the light at an unsightly angle to use mirror. The switch is located conveniently so the hand finds it instantly in the dark.

The back is so formed that the hand grasps the light naturally, without cramping—and turns the light in any direction—up, down, right, left, front, or back—with ease. The case is absolutely dust and moisture-proof. A focusing device permits the use of any size bulb.

The bracket—an exclusive Stewart feature—not only permits turning the light in any direction, but also fits any windshield.

Both its handsome appearance and complete utility recommends it. It has high quality and finish all the way through. Its low price \$5.00—is not an indication of quality, but a tribute to the Stewart Organization, which makes quality accessories at popular prices possible through large quantity production.

And so it is with all Stewart Automobile Accessories. Each, because of sheer merit and high quality, deserves a place in the equipment of every automobile.

Stewart Accessories are sold by leading accessory dealers, jobbers and garages everywhere.

## Offered Aid of Allies Not Accepted by Aircraft Authorities

Foreign Missions Sent to America to Give Advice  
and Assist in Work Are Not Consulted

### SUGGESTED SUBJECTS FOR A REAL AIRCRAFT INVESTIGATION

By Allen Sinsheimer

**W**ASHINGTON, Sept. 10—Although airplane matters have been very quiet since the Labor Day holiday, the recent cancellation of the Caproni contract for manufacturing bombing planes and other steps in the selection of types of planes to build have added to the confusion of the situation and force many to ask why an investigation should not answer some of the questions with regard to types of planes that have not been touched upon in the Senate Committee report.

The Foreign Aviation Missions now in this country to assist in the airplane program are amazed and quite at sea because of many things that have recently happened in connection with the work and they see very little if any use for remaining in this country when their recommendations are given so little consideration.

It is gossiped in Washington circles that an investigation which shows something will be worth while and very desirable. There are many subjects that might be answered, in fact, that should be answered, whether an investigation is necessary to secure these answers or not. There should be answers forthcoming which would explain the reasons for some of the following:

1—The 8 months' delay and indecision on the Nieuport 15-metre scout.

2—The selection of the Bristol scout discarded long ago by Great Britain.

3—The large orders for the 80 hp. Rhone engines.

4—The selection of the SE5, long since discarded by England.

5—The refusal by this country of thousands of SE 5's offered by England.

6—The complete cancellation of the Caproni program.

7—The bewilderment and discouragement of our Allied air experts in this country.

8—The apparent lack of regard for the opinions of the Allied aviation missions by our aeronautical divisions.

9—The reports that numerous engineers are given carte blanche to improve their inventions while discrediting all other suggestions.

10—The frequent charges that there are too many engineers with individual preference, too many authorities and too little decision.

Eight months ago following a conference between American and foreign heads of the air divisions, decision was made to adopt the Nieuport 15-metre scout for training pursuit pilots in this country. It was to be equipped with the 80 hp. Le Rhone engine.

After 8 months of absolute inactivity, it has been announced that the Nieuport program is abandoned and that the British Bristol scout has been adopted in its place. The Bristol scout is 3 years behind in the British program. It has been discarded for a new Bristol far superior. The Bristol scout has a speed of 80 m.p.h. and a ceiling of 10,000 ft., while the Nieuport has a speed of 106 m.p.h. and a ceiling of 17,000 ft. equipped with the same engine.

British experts join in the declaration that of the two machines the Nieuport is far superior.

French officials are dumfounded at the substitution of the Bristol for the Nieuport. They are at a loss to understand it. It is reported here that the chief reason for using any such machine as the Bristol is the large order placed some time ago for the 80 h.p. Le Rhone engines. The authorities do not know what to do with the quantities of these engines, it is said, and are therefore taking on the Bristol scout.

### England Discarded the SE 5

Recently, announcement was made that the SE 5 was officially adopted for the American airplane program. As soon as this announcement reached England, a very high British official cabled that England had long discarded this plane and had 5000 or 6000 on hand which would be sold to this country reasonably. Our officials replied refusing the offer, stating that we will build them in great quantities and have no use for the several thousand on hand in England. With no explanation, this reply leaves the British confused.

The SE 5, as was told before in these columns, has not only been discarded by England as long ago as September, 1917, but was discarded for the SE 5 A, which had a higher speed and all around better performance and which in turn was superseded by the Sopwith Camel, discarded for the Sopwith Dolphin, replaced by the Sopwith Snipe. Each of these machines in turn has been regarded as superior to the preceding one by the British experts. We have selected a machine in the SE 5 which has been replaced four times over and which was called obsolete 1 year ago.

### Reasons for Caproni Cancellation

Politics and business influences are rumored to be the cause of the Caproni program cancellation. Although it is conceded by everyone that bombing planes in great quantities will certainly hurry the end of the war; although Caproni planes tested with Liberty engines have been proven even better than the Caproni equipped with the Fiat engine; although Italian experts from the Caproni plant have been in this country for months, there has been only delay and indecision and now, finally, we have complete cancellation of the plans for Caproni plane construction. And the Italian authorities appeared to be as much at a loss to understand the cancellation as the average citizen.

The British, French and Italian air missions are, of course, delicately situated and unable freely to express opinions, but it is an open secret that they are alarmed and discouraged with American air

activities. Many valuable men, needed in their own countries, sent here to give us the benefit of their experiences, sit in their offices, unable to gain hearings with the American officials, wasting their time O.King blueprints that are never used and rejecting others embodying numerous foolish practices. When they can be induced to talk they tell of the many engineers who will approve only their own ideas, of the lack of definite authority, of the inability to make a decision and stand by it.

### Allies Approve Liberty Engine

The Allied experts all approve our Liberty engine. They will take all they can get of them. They are amazed at our great production which is steadily climbing toward the peak. But witnessing this remarkable performance on one hand, thoroughly converted to our standardization and plans for few models, they are unable to connect the efficiency shown here with the confusion that exists as regards all of the other operations.

They are unable to understand the speedy engineering and production of the Liberty engine and the principles of standardization, with our delay and procrastination in plane production and our present plans which point toward a program of many types of planes.

One engineer sent to this country was at first an ardent believer in quality as against quantity. He has changed his ideas. After witnessing the hampered production here, due to the constant improvements suggested to their inventions by our engineers who have been given carte blanche, he has turned to the German plan of producing few types in great quantities. His investigations over here, his contact with our officials and his experiences have led him to make suggestions which he cannot personally offer in his official capacity.

### Suggests a Business Head

He suggests the appointment of a thoroughly capable business man, "one who has had to do with automobile production," to the head of all aircraft work with absolute power.

This man should then call together the British, French and Italian airplane engineers for conference with the American engineers to decide on three types of machines or as many as they decided necessary. He believes in the use of three types:

- a—Pursuit machines (single seaters).
- b—Artillery and reconnaissance machines (2-seaters).
- c—Long distance bombing machines (double engine, 4 or 6 seaters).

In collaboration with these experts, he further recommends the fixing of a schedule of performance necessary for the machines of each type before they can be adopted. For example:

A pursuit machine before adoption and production must exceed certain speeds at certain heights, climb to specified heights in a certain number of minutes and display certain endurance powers.

After the schedules of performance have been decided upon they should be duplicated and copies sent to each airplane firm in the country. The firms

themselves could then design their own machines to meet or exceed the performance.

In consequence of this plan there would be different firms in all sections of the country striving to produce the best possible machines, some building pursuit planes, some bombing planes and others reconnaissance planes. When the machines are finished the firms would notify the aircraft headquarters which, in turn, would order them sent to a central testing ground.

The result would be a large number of all the necessary types of planes awaiting the tests. The best of each type would be selected after thorough trials, the machine exceeding the schedule over all its competitors being the one selected. This one in each type would be universally adopted as the standard plane and put into production.

A plan of this sort would eliminate design of all planes by a few men as is now the case. It would prevent the constant tinkering and attempts at improvement which hinder production. It would insure a machine equal or better than the requirements set by the original conference, and while this plane is in production and in service further improvements which would not hamper production or newer and better designs of planes could be studied for the later program.

Whether these suggestions are adopted or not,

there must be some radical changes. Recently the chief official of the military air section testified before Congressmen that the SE 5 is a two-passenger machine, when as a matter of fact it is a single-seater. He compared it to the Spad, although it is completely different in performance, appearance and horsepower.

With the airplane program vitally important in the successful prosecution of the war, it is most urgent that we have men at the head of this work who thoroughly understand it and that we have some definite policy under the control of such an executive.

A secretary of Aircraft with full power to act, versed in internal combustion engines, broad enough to appreciate the value of the foreign experts, combined with some such plan and organization as is suggested, will probably insure speedy and successful fulfillment of the airplane program. Certainly it could not allow for the existing confusion and delay.

Without doubt many other apparently unreasonable activities like those and equally bewildering and confusing will be found. The men responsible must be removed. The proper organization and plan must be determined. Thoroughly trained competent men must direct the work. In this way only can we achieve the success that is expected:

## Keeping Track of Labor Turnover

In Plants Where Semi-Skilled Men Must Be Trained to Meet Labor Needs, a Careful Compilation and Analysis of Turnover Records Is Worth Many Times the Expense Involved

By E. H. Fish\*

**M**UCH has been said in the past few years regarding the high cost of a high labor turnover. There has been a tendency to attack that high cost blindly, with the idea that a reduction by whatever means must be an economy. There are, however, many cases in which the employer is much better off to be rid of an employee, and many cases in which the employer ought to wish a departing subordinate Godspeed and good luck.

No single figure, no matter what the definition of labor turnover may be, will give the general manager a true idea of what is going on in the shop or office. An analysis will.

It is probable that most concerns will find that certain departments hold their men and others do not. They will usually find that married men stay longer, on the whole, than unmarried. If the work is seasonal they sometimes find that married men shun their places. They find that men who have a deep-rooted feeling that they wish to live in that particular city stay better than men who have been in the habit of roving.

There are then two principal things which determine the analysis: the department, and the cause of leaving; or, more important yet, the reason for staying. The

division by departments should be fine enough to reach the foremen, whose influence is most felt by the workmen. This is different in different shops. In some the department head is in close enough contact with the men so that any difficulty with the straw boss comes immediately to his attention. In other cases the straw boss or working foreman is the man who really determines the status of his subordinates.

Whichever it may be, we need to know definitely how well men stay under certain personalities. A great many foremen take the ground that with the dilution of labor going on all around us they cannot be blamed for the rate at which subordinates leave them. They cannot be held responsible for the whole turnover in their departments, but they themselves ought to wish to know how their departments compare with those under other foremen.

### Three Classes of New Men

It is also interesting to keep watch of the new men, dividing them into three classes: those new to the shop, those who have worked there in the past and are rehired, and those who are transferred from one department to another. We are interested in these items because the number of men rehired is a very good indication of the

\*Employment Manager, The Norton Co.

esteem in which the shop is held, and the number transferred is a good indication of the attempt to steady employment. No shop is quite so well able to get a high-grade of help as the shop which has a reputation for taking care of its men.

Most of us are children in business, as otherwise we would probably not be good mechanics, and we crave a certain degree of paternal treatment. To get this information it is well to classify the transfers as promotions, demotions on account of health, and those which are merely for departmental fluctuations. It is also our practice to classify the new men and those rehired as skilled, learners, and laborers. This classification, in these times, is especially desirable to show to the general manager what a large proportion of his new men must be trained in some way. Knowing the number, he may see more clearly whether it will probably pay to establish a vestibule school, or a school for training foremen to teach.

Many foremen take the unfortunate ground that once a man leaves them he has burned his bridges behind, and cannot return. The analysis shows who they are. A great help in rehiring is to have the man rated when he leaves, so that a glance at his folder, if records are kept that way, will show whether he left in such a way that he should be considered for immediate re-hiring, or whether he should be warned that he could not get back easily unless he gave a reasonable notice. This, however, depends on other conditions in the shop. There are many places where men do not give notice when they intend leaving, for the simple reason that they know from the past experience of others that they are liable to be told to "get to h— out right now."

There are other places where, if a man gives notice, he can get all his money the day he quits, which is productive of a high turnover, because every time a man feels that he would like a little more money than he ordinarily gets he gives his notice, and goes to work for our competitor the next Monday. If these things are going on in the shop unknown to the general manager, a few statistics will set him on their track.

#### Analysis of Reasons for Leaving

The most important thing, however, is an analysis, by departments, of the reasons for leaving. If the management knows why men leave, and in what numbers, he can tell with fair certainty how much money he can spend to cure the trouble. It is not easy to find out why men leave. Usually, it is a combination of reasons. The last one, the straw that broke the camel's back, may be the one that is given, while one that is not uppermost in the man's mind may be the fundamental one. No system of tabulation is of any value unless the management is confident that the interviewer who sees the workman has gotten to the bottom of the causes; and quite often, when he has reached the bottom, and can begin to build up on a solid foundation, he is able to retain the services of the man.

These times, the first reason we expect to see advanced is low wages. Probably half the men who leave will allege that they can get more money somewhere else. Many times they can. None of us like to knock our neighbors, especially if we both belong to the same employment managers' association. We may be very certain that this particular man cannot earn what he claims, or, if he can do it in a competitor's shop he can do it in ours, too, just as well as to move over there.

The proportion of the turnover which is found after careful inquiry to be due to the ability of our employees to get better-paying jobs, compared with the number of men returning to us after having been away to try another place, is what should determine when it is best to

raise wages. This proportion will, of course, be different for every different shop and for varying conditions in the one shop, depending on whether the policy of the company is to pay for the pick of the available workmen, or whether it prefers to keep its payroll low and depend on excellence of foremanship to produce results.

Working conditions are the next thing to tabulate. By this we mean whether the work is dusty, dirty, heavy, wet, dangerous, or otherwise disagreeable and unsafe. A high proportion of labor turnover may justify the expenditure of considerable sums of money for improvement, while a low rate may prove that employees do not object to the prevailing conditions so much as the superintendent might.

One of the elusive things is the leaving due to the coolness of the social atmosphere. An office man is apt to think of this attitude as his prerogative, and not to grant the shop men the sensitiveness to notice it. It is usually one of the last straws that determines whether a man will put up with other things. It is just this one straw, however, that if removed might help keep men on the job. Other divisions under which leaving should be tabulated are housing, transportation, commissary, preference for another line of industry, living nearer home, and, naturally, now, entering Government service.

#### Recording Reasons for Discharges

Discharges should also be classified. If a certain department shows a large number of men discharged as "trouble breeders," the foreman may be suspected of having caused the trouble, or possibly he may be using it as a cloak to his desire to get rid of men on personal grounds. We do not tabulate the latter, as we feel that it should not be allowed. If a foreman does not like red-headed men he should say so when he sends in his requisitions.

The turnover due to unavoidable causes, such as death, protracted illness, marriage of female employees, etc., is so small as to be hardly worth recording except for the sake of completing the record; but it is also so small as to make the recording a trivial expense.

This brings us to a vital question: How much can a firm afford to pay for keeping vital statistics like these? The answer is, "It depends." If the works are run entirely by unskilled laborers, if the supply is ample, then there is little good to be obtained. If the plant is operated almost wholly by skilled men, who come already well trained, and the supply is ample, there is no great object; but if the plant is in the condition that almost every shop in the country is in to-day, where the work is being done by semi-skilled men who are being trained on the job at great expense, or in separate vestibule schools at less expense, then the saving to the shop of even a few men who would otherwise have to be replaced at anywhere from fifty dollars each up, then the profit is so great that the expense sinks out of sight. Our experience is that a good man on the job in a plant with four thousand men can save his salary and the expense of this office about ten times over.

#### New Duplex Instruments

IN its new catalogue on Instruments and Relays, just published, the Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa., announces two new duplex instruments for battery charging, marine, dental, telegraph, telephone, farm lighting, and other compact instrument panels where direct-current is involved.

These duplex instruments consist of any two standard Westinghouse type AW or type FW instruments desired, mounted in an attractive dull-black metal case. The type AW instruments have round open faces, 8 in. in diameter, with glass cover and rear mounting studs; the type FW have 5-in. faces.

# Process Refining Systems Would Increase Gasoline Production

Cost of Installing Such Apparatus Would Be Returned in 80 Days—Present] Need Is for Increased Output Rather Than Curtailed Use

**F**IGURES on gasoline production and consumption given out by the Fuel Administrator to-day showing that since April 1, 1918, there has been a decrease in gasoline reserves of 4,119,000 barrels (barrel contains 42 gal.) must be interpreted somewhat differently from what these figures would indicate, in that gasoline is a seasonable product with a maximum consumption taking place during the period of April to September, inclusive, and with the peak load of consumption coming in June, July and August.

To understand the gasoline situation it must be remembered that the high point of storage of gasoline generally comes in April and that this storage stock gradually falls off until October, when it starts building up again to the following April.

The gasoline stock in storage during three periods of the present year bear out these figures:

	Barrels
January 1 (in storage).....	9,902,000
April 1 (in storage).....	15,787,000
August 1 (in storage).....	8,648,000

According to the Fuel Administrator, the daily deficit or loss in stocks approximates 11,000 bbl. of 42 gal. each. The deficit in the territory east of California is 3000 bbl. per day and in the California territory 8000 bbl. per day.

These figures, given out by Fuel Administrator Garfield, were in reply to the Lodge resolution asking that figures be furnished to show the supply on hand. The complete figures for the territory east of California and also for the California territory are given herewith as presented by the Fuel Administrator.

These fuel figures are doubtless responsible for the recent requests for automobilists practically to discontinue the use of motor cars on Sundays. There is scarcely a motorist in the

country who does not wish to conserve as may be necessary, but there are other viewpoints on the fuel situation which we believe the Fuel Administration should take recognition of and attempt to supply the necessary gasoline, not all by curtailment, but rather by increased production.

This can be accomplished by the use of a process system of manufacture, which systems are familiarly known as pressure systems and in which a pressure ranging from 75 to 110 lb. per sq. in. is used in the stills and where the temperature varies from 700° to 750° Fahr., a temperature high enough to crack the crude into gasoline and thereby greatly increase the production of gasoline from crude.

There are 30 or 40 of these process systems of gasoline refining, several of which are very practical and valuable. With three or perhaps more of these processes it is possible to double the output of gasoline from a given quantity of crude. With what is known as the skimming method, a gallon of crude oil will yield approximately  $\frac{1}{4}$  gallon of gasoline, but with the process system, refining this same gallon of crude will yield approximately  $\frac{1}{2}$  gallon of gasoline.

At present, scarcely 20 per cent of gasoline is produced by the process system, which means that on 80 per cent of the crude used we are literally securing but 50 per cent of the gasoline from it that we should be securing. The Standard Oil Co. has been a leader in developing the process system, this particular system being the Burton, developed by Dr. W. M. Burton, chief chemist of the Standard Oil Co. of Indiana, whose refinery is at Whiting, a short distance out of Chicago. This company began manufacturing under the Burton process 7 or 8 years ago and has since licensed practically all of the other Standard Oil companies.

The majority of the other big refinery interests have not  
(Continued on page 483)

# The Bennett Centrifugal Air Washer

Combines the Centrifugal Principle of Separating Dust from Air with the Water-Washing Principle

**T**HE Bennett centrifugal air washer, a new product of the Wilcox-Bennett Carburetor Co., Minneapolis, Minn., consists essentially of a Bennett air cleaner suspended within a cylindrical casing containing a quantity of water. This water is made to revolve within the container by the whirling action of the air drawn into it from the suction of the carburetor. The water rotates because the air is drawn into it tangentially through two spiral tubes in the inner circumference of the casing.

Referring to the sectional view of the air washer, the dust laden air enters as shown and passes into the water compartment through openings in the spirals at A. The rapidly whirling air causes the whole mass of water to revolve so that it piles up against the sides in approximately the position shown by the dotted line. This completely submerges the lower ends of the spirals so that all the air must pass through the water before escaping upward into the openings C of the inner air cleaner.

The air cleaner has three spirals on its inner circumference through which the air and entrained moisture pass. The centrifugal action set up in the inner cleaner completes the cleaning of the air and also throws down any drops of water that have been picked up in the air. These water drops are thrown downward and back into the water container through the open end of tube B. This reduces the humidity of the washed air and also prevents excessive water consumption. The clean air, after passing out of the spirals in the inner cleaner, escapes upward and out through the elbow at the top of the carburetor air intake.

As long as there is any water in the container the whirling of the water keeps the end of tube B (which is very close to the bottom of the container) sufficiently open for the downwardly projected water to re-enter the reservoir. However, if the water supply is allowed to totally evaporate, enough mud and dirt will settle under the open end of B to seal it, so that even if the container runs dry, the inner air cleaner will collect the dust as a dry air cleaner. Of course, if the water container is dry and also clean, no such cleaning action is possible unless opening B is closed.

The water compartment is filled to the top of the filler cap.

Section through air washer

At normal summer temperatures one filling should last a full day with a tractor in the field.

To clean the accumulated mud or dirt from the air washer, nuts D are loosened, the water reservoir is turned to free it from the catches on the studs, and is then removed and cleaned thoroughly and frequently. It is then replaced and refilled with water. The air washer when used where there is much dust, should be cleaned every day.

## Cadmium as Substitute for Tin

**T**HE possibility of using cadmium as a substitute for tin in solder appears promising. Among others the composition containing 80 per cent lead, 10 per cent cadmium and 10 per cent tin has shown particular promise. No difficulty is anticipated in connection with the production of cadmium on a commercial basis at a price considerably less than that of tin as soon as it has been demonstrated that its use for this purpose can be generally extended.

Bennett air washer complete and in parts

*New engine test house of the Duesenberg Motors Corp.*

## A 900-Hp. Dynamometer Installation

New Test House of the Duesenberg Motors Corp. Has Several Features of Novelty Relating to Water Cooling, Exhaust Disposal and Dynamometer Tests of Mammoth Engines

**A**IRCRAFT engine testing confronts the engineer with problems which differ from those of automobile engine testing chiefly because of the enormous powers involved. While the 1000-hp. mark has not yet been reached in aircraft engines, its attainment is already in sight. The majority of the engines now being produced in this country for aircraft work range over 400 hp. on the brake, which is more than ten times as much as the average automobile engine. This comparison is here made because in the past standard testing equipment has been largely designed for automobile engine tests.

Obviously, engines for aircraft must be more rigidly tested than those for any other purpose, and the departments letting the contracts issue detailed specifications of the tests each engine must pass before it will be accepted. In addition to routine tests of its regular stock product, an engine factory carrying on development work must also conduct tests on experimental engines, and these latter call for somewhat different equipment than the routine tests.

In regular routine tests it is desirable that the conditions of actual use be duplicated as nearly as possible. Formerly it was customary to test aircraft engines with plain clubs which are really a form of fan dynamometer. By plain club is meant a beam of square or rectangular cross section which is secured to the engine crankshaft in the same manner as the propeller. Now, however, clubs with their ends given a form resembling propeller blades are used, to produce the identical condition of end thrust

on the engine bearings to which they are subject in flying.

One of the most modern airplane engine testing departments in the country has just been completed by the Duesenberg Motors Corp. at Elizabeth, N. J. It is installed in a steel and brick structure on a concrete foundation, 240 ft. long by 67 ft. wide. A large part of the side walls is of glass, and efficient lighting and ventilation are further assured by a monitor roof construction.

As one enters the building, on the right there is an office where the test records will be kept, and directly behind it an oil storage and filter room. To the left of the entrance are a chemical laboratory (corner room) and a physical laboratory, where all material furnished the company for the manufacture of its engines may be analyzed and subjected to mechanical tests. In the physical laboratory, in addition to the usual testing machinery, are installed a number of light machine tools for machining up test specimens, and a furnace for heat treating them.

Passing through the entrance way between these two sets of rooms, one enters the main test room, which extends the whole width of the building and 176 ft. in length. This room is equipped with 22 test stands arranged in two rows, one along each wall. The test stands are of the cradle type, the power developed by the engines being determined by measuring, on a scale, the torque reaction of the dynamometer cradle. The cradle is supported by a heavy stub shaft at one end and in a semicircular guide at the other. Secured to the cradle

*Showing one of the test cradles with its equipment and one of the large size clubs used for testing engines*

are two arms which extend in opposite directions, and from the ends of these arms depend steel bars, of which one serves to transmit the pressure of the torque arm to the scale platform while the other merely balances the former. Mounted above each testing stand is a chain hoist. Engines are brought into the test room from the assembling department on industrial trucks, raised by the chain hoist and slid into position on the cradle of the test stand.

Each test stand is provided with its own fuel, oil and water supply and with an electric starter to start the engine. The gasoline tank is mounted high on the wall and feeds by gravity. It can be conveniently filled by means of a pump driven by a separate electric motor, mounted on the wall below the tank. Oil tanks are placed on the floor close to the stand and there is a water tank high up on the wall through which the cooling water is circulated by the pump on the engine.

It can be readily imagined that a 400-500-hp. engine running under full load will quickly heat up an ordinary wall tank full of water, and a means of abstracting heat from the tank had to be provided. This problem was solved in an interesting way by the erection outside the building of a concrete cooling fountain, 50 ft. in diameter, of which a view is shown herewith. The whole cooling system has a capacity of 75,000 gal. A standpipe rises at the center of the fountain, through which the water is forced by a pump driven by an electric motor.

The top of the standpipe is surrounded by a mushroom-shaped plate, and as the water gushes from the pipe it is spread out in an even film. From this plate it drops onto successive annular surfaces of concrete, the film getting gradually thinner and the speed of the water slower as it spreads out, and from the last annular surface it returns to the basin below. Each cooling tank in the test room is connected in circuit with the electric motor pump and cooling fountain, and when the pump is running the water in, the cooling tank is being constantly renewed. The same water, of course, is used over and over, and a considerable economy is effected by this means.

In order to safeguard the men working around the engine under test, a heavy wire screen is placed between the engine and the propeller or club.

A problem of considerable importance is that of disposing of the exhaust products, for with 20 or more engines of several hundred horsepower each running under full load, it would take but a short while to vitiate the air to such an extent as to make it impossible for the testers to remain within the room. In the Duesenberg test room the exhaust gases from each engine are directed through an overhead funnel into a large underground duct which discharges into an 85-ft. stack. Natural draft is depended upon to suck all gases into the funnel and carry them through the underground duct and up the stack. There are two of the stacks, one for each row of test stands.

*The cooling fountain serves the function of a giant radiator*

*View in the dynamometer room, showing three electric dynamometers coupled together*

At the rear of the main test room is the dynamometer room, in which are installed three Sprague electric dynamometers capable of absorbing up to 300 hp. each. These machines are arranged tandem fashion and may have their shafts coupled together for tests of engines of over 300 hp. At each end of the set of dynamometers there is an engine stand, one of these stands being arranged chiefly for tests of very large engines requiring two or even all three of the dynamometers to be coupled together.

It was found that the shafts of the standard dynamometers were sufficiently rugged to permit of this method of connecting them up, but a special coupling had to be designed for the dynamometer closest to the engine. Electric tachometers are mounted on the dynamometers and in addition there is a Schaeffer & Budenberg tachometer driven by belt.

While the writer was at the plant there was a large engine on the dynamometer stand which was fitted with

a compressed-air starter. However, provisions are also made for starting the engines under test electrically, through the dynamometers, running as motors. The current used for this purpose is taken from alternating current mains and is converted into direct current by a rotary converter installed in the dynamometer room.

The energy developed by the dynamometers is absorbed in resistance grids located back of the switchboard on the rear wall of the building. These grids are in six sections and each is capable of absorbing 200 hp. An electric motor with a small propeller mounted on its shaft is supplied with current from the dynamometer and is used to blow a current of fresh air over the engine while under test.

The Duesenberg testing department is remarkable chiefly for the fact that it contains equipment for testing engines up to 900 hp. output, this being undoubtedly the most powerful dynamometer installation in any aircraft engine plant in the country at the present time.

## An Argentine-Built Body

*THIS* photograph shows a car with a body built by Fehling Bros. of Buenos Aires, Argentine Republic. Fehling Bros. are importers of American chassis, and formerly had special bodies built to order in the United States; but they claim that the service was so poor that they were compelled to install their own body-building department, and this is one of the first bodies completed by them.

*Elevation, partly in section, of the Mercedes 180-hp. aircraft engine of 140 mm. bore and 160 mm. stroke*

# The 180-Hp. Mercedes Aircraft Engine

A Development of the 160-Hp. Model, Having the Same Cylinder Dimensions—  
Compression Increased and Many Details Redesigned  
—Fuel Test Results and Table of Data

**E**NGINEERS of the Daimler Motor Co. have redesigned the 160-hp. six-cylinder Mercedes aircraft engine and have succeeded in raising its output to 180 hp. The following report, issued by the Technical Department (Aircraft Production) of the British Ministry of Munitions, is based on an examination of engine No. 35254 taken from the captured German Albatross biplane D.5.A. (G.97), which was shot down by anti-aircraft fire in the 5th Brigade area on Nov. 14, 1917, and the accompanying data on the design of the engine and the particulars of its general performance, have been compiled from results of tests carried out at the Royal Aircraft Factory.

The 180-hp. Mercedes engine is the first engine of a new type to be used in service since the advent of the 260-hp. Mercedes engines in the early part of last year. These 260-hp. engines were apparently so successful that the 160-hp. type have since been remodeled so as to introduce several of the leading features of the 260-hp. practice. The result is seen in the 180-hp. model, with which this report deals.

## Comparison Between Old and New Designs

It necessarily follows from the above that this report will partake more or less of the character of a comparison between the 160-hp. and 180-hp. models. Frequent reference, therefore, is made in the text to the 160-hp. engine.

In many respects the design of this new engine is similar to the 160-hp. Mercedes, which is now obsolescent. The cylinders are of the same construction and of the same bore and stroke as the 160-hp., i. e., 140 mm. x 160 mm., as also are most of the reciprocating parts; in fact, this engine might well be termed "The New 160-hp. Mercedes."

Briefly described, the 180-hp. Mercedes is a combination of the 160-hp. and the new 260-hp. Mercedes engines, and in view of this fact it will be unnecessary in this report to deal at length with the details of the design of those parts which are identical with the components of the above-mentioned engines, of which fully detailed reports have already been issued, and the design of which is now well known in this country.

In comparison with the standard type 160-hp. Mercedes, the new engine shows a marked improvement, both in the design as a whole and in its general performance during power and consumption tests, and as a comparison between the two engines the following comparative table of the leading particulars of the engines is herewith given:

	160 hp.	180 hp.
Bore .....	140 mm.	140 mm.
Stroke .....	160 mm.	160 mm.
Compression ratio .....	4.50:1	4.64:1
Average b.hp. and speed .....	162.5 at 1400	174 at 1400
B.M.E.P. (lb. per sq. in.) .....	102.0 at 1400	109.1 at 1400
*Total weight of engine (dry) ..	618 lb.	635 lb.
Weight per b.hp. ....	3.80 lb.	3.65 lb.
Fuel consumption per hour ....	94.2 pints	94.83 pints
Fuel consumption per b.hp. hr. .	.58 pint	.545 pint
Oil consumption per hr. ....	5.0 pints	7.3 pints
Oil consumption per b.hp. hr. .	.031 pint	.042 pint
Inlet valve opens .....	2° L.	T.D.C.
Inlet valve closes .....	35° L.	40° L.
Exhaust valve opens .....	63° E.	40° E.
Exhaust valve closes .....	13° L.	10° L.
Ignition timing (fully advanced)	30° E.	30° E.
Delivery of water pump .....	41.4 gals. per min.	

\*This weight is weight of engine (dry), excluding propeller hub and exhaust manifold.

The six separate cylinders are exactly the same construction as those used in the standard 160 hp. Mercedes engines, being built up entirely of steel, with the valve pockets threaded and welded into the cylinder heads, and the water jackets of pressed sheet steel welded in position. The pistons also follow the standard Mercedes practice and are similar to those used in the 160 hp. engines, being constructed with concave heads machined from steel forgings, which are screwed into the cast-iron skirts of the pistons and welded in position.

Three rings are provided above the piston pins and one ring below, which is situated at the base of the skirt. The piston pins are carried in lugs machined in the lower part of the steel piston crown. The compression ratio, it will be noticed, is slightly higher in the new 180-hp. engines, being 4.6:1 as compared with 4.5:1.

The H section connecting-rods with their floating cast iron piston pin bushes also follow the usual Mercedes practice, and are identically the same as those used on the 160-hp. engines, and the whole of the camshaft vertical driving shaft and also the water and oil pumps driving gear is similar to the 260-hp. engines.

No alteration has been made in the general design of the crankshaft from the standard 160-hp. type. The leading dimensions, clearances and method of lubrication of the journal and connecting-rod bearings are the same, as shown in the general sectional view of the engine.

The crankcase while following the general construction of the 160-hp. engines, also resembles in many ways the 260-hp. type. The usual Mercedes practice of casting the lower half of the main bearing housings integral with the bottom half of the base chamber, and also the method of holding down the cylinder by long bolts which pass through the base chamber top half and secure the halves of the crankchamber, is adhered to.

## Valve Gear New

The single inlet and exhaust valve of each cylinder, which work at an angle of 15 deg. to the axis of the cylinder, are interchangeable as in the 160-hp. engines and are of similar design. The valve operating gear is, however, of new design and follows more the construction of the valve gear on the 260-hp. Mercedes engines. General details of this construction and working of the valve gear are shown in the sketch.

It will be noticed that the rocker arms and their spindles are now integral, being machined from steel forgings. The camshaft casing is constructed entirely from malleable-iron castings, and the valve rocker spindles work in direct contact with the malleable iron, no bronze bushes being provided as bearings for the rocker arm spindles, and the covers of the camshaft casing form the top portion of the rocker spindle bearings.

The rocker spindles are hollow, and are lubricated through two holes drilled radially in the spindles by oil thrown off the revolving cams into the two holes drilled in the rocker arm carrying the cam roller.

This design of valve gear is undoubtedly a great improvement on the arrangement adopted in the 160-hp. Mercedes, the construction of which is well known, having the rocker arms working through slots in the camshaft casing, which are provided with felt-packing strips and baffle plates for retaining the oil in the camshaft casing.

The camshaft is of similar design to the 160-hp. Mercedes, and the casing is supported on long studs which are screwed into the head of each cylinder.

Valve gear and air pump

Air pump

With regard to the valve timing, this, it will be noticed, is different from the standard 160-hp. Mercedes, as shown in the comparative list of leading particulars. The valve lift has been increased from 0.440 in. on the 160-hp. engines to 0.452 in. Only very minor differences occur in the actual dimensional details of the half compression gear in the new engine. Details of this mechanism are now well known; the general design is, however, clearly shown in the general arrangement sectional drawing of the engine.

#### Carbureters

No alteration has been made in the design of the twin-jet dual carbureters. Both carbureters are enclosed in a cast aluminum water jacket, which is coupled at the bottom by a water pipe to the delivery pipe of the water pump at the top of the water jacket of the rear cylinder to the top portion of the water jacket of the carbureters.

Each carbureter feeds three cylinders by a branched induction pipe of steel tube which is lagged with asbestos cord and bound with adhesive tape. The throttles are, of course, interconnected, and are operated by a cable and also by a control lever and rod. The float chambers are of ordinary design, but are fitted with separate filters attached to the bottom of each float chamber, which are easily detachable. These filters are provided with needle-valve drain cocks. No compensation arrangement is provided for altitude control. The bore of the main jets is 1473 mm., and the bore of the pilot jets .558 mm., which is the same as in the 160-hp. Mercedes carbureters. A semi-diagrammatic sectional view of one of these carbureters is reproduced for reference.

The air-intake to the carbureters is taken through the passage cast in the central portion of the top and bottom halves of the base-chamber, which forms an air chamber between the front and rear oil pumps in the lower portion of the bottom half of the base. Air enters the central air chamber through two holes cast in the sides of the chamber and

also warm air through a large diameter pipe leading from the central portion of the top half of the crank chamber.

#### Camshaft Drive

The method of fixing the camshaft driving bevel at the top end of the vertical shaft, as shown in the sketch, is unusual. This method is similar to that adopted in the 260-hp. engines, and is so designed as to allow of a certain amount of vertical adjustment of the bevels. The driving end of the vertical shaft is machined and ground parallel, 21 mm. diameter, and is fitted with a key, which fits in a keyway in the driving bevel; a ground taper on the bottom extension of the bevel, which is split by four saw cuts, and into which screws a ring nut, locks the bevel securely in position on the vertical driving shaft.

In the old 160-hp. Mercedes engines the camshaft driving bevel on the vertical shaft is fixed by two bolts in the split extension of the bevel which is fitted on to a ground taper on the vertical shaft.

Referring to the sketch of the vertical shaft, it will be seen that the bottom end of the shaft is carried on a "Skefko" universal bearing, which is mounted inside a steel sleeve, carried at the rear end of the crankcase, and is driven off the floating bevel gear on the rear end of the crankshaft in the usual way.

#### Lubrication

The old 160-hp. type multiple-plunger oil pump has been replaced by the larger pump, similar in design to the 260-hp. Mercedes pump. The oil pump is attached to the bottom of the rear oil sump or reservoir, at the rear end of the base-chamber.

The functions of the oil pump are perhaps most clearly demonstrated in the diagrammatic sectional drawing and in the sectional sketch of the pump.

Briefly described, the functions of the oil pump and the system of lubrication may be sub-divided into three circuits.

(a) *The main pressure circuit*, in which oil is drawn from the main oil sump at the rear of the base chamber and is forced to the main crankshaft journal-bearings and connecting rod bearings, and also the camshaft bearings.

(b) *The supplementary pressure system*, which works in conjunction with the main high-pressure system, in which two auxiliary plungers of the main oil pump draw a small charge of fresh oil from the service oil-tank at every stroke of the

Intake side of Mercedes 180-hp. aircraft engine. This illustration clearly shows the method of supporting the carburetor on the crankcase and drawing the air through the latter in order to heat it

Camshaft driving pinion at attachment and arrangement of ball bearing at bottom end

SKF twin race bearing.

Water pump

The carburetor

pump and force the charge into the main circulation system.

(c) The suction or scavenger circuit, which supplies the main oil sump from the auxiliary drain sump at the front end of the base chamber, the working oil level being maintained in the rear sump by an auxiliary suction pump which draws off the oil above the oil level through an overflow pipe and returns it to the oil tank.

An oil sight level indicator is provided in the side of the rear oil sump.

Full details of the functions and operation of this somewhat complicated oil pump are given in the previous report on the 260-hp. Mercedes engine.

#### Ignition

Two Z.L.6 type Bosch magnetos are fitted at the rear end of the engine and are driven directly off the camshaft vertical driving shaft by bevel gears, as in the 260-hp. engines.

Ignition is by two Bosch 3-point plugs fitted to each cylinder, one on either side of the cylinder below each valve head, and the h.t. cables are carried as usual in fiber tubes attached to the cylinders.

The ignition timing is fixed at the same period as in the 160-hp. engines, i.e., 30 deg. E., and the speed of the magnetos is 1.5 times engine speed. Firing order: 1, 5, 3, 6, 2, 4.

The water pump in the old type 160-hp. Mercedes engines is situated above the magneto drive, and is driven directly off the vertical camshaft driving shaft. In the 180-hp. engine the standard 260-hp. type water pump has been adopted. This is now driven, as in the large engines, by a dog clutch off the bottom end of the lower vertical shaft, which also drives the oil pump worm driving shaft, as shown in the sectional view.

Diagrammatic section of oil pump

The water pump spindle is provided with a spring-loaded face-washer of steel in place of a gland, and the spindle is lubricated by hand, as in the 260-hp. engines, by a large screw-down grease lubricator accessibly arranged on the pilot's seat. Details of this water pump are clearly shown in the sketch.

This is of a new design, and is now driven off the front end of the camshaft, as in the 260-hp. engines. The piston and barrel of the air pump are made of cast iron, and the piston is operated by a small connection rod of bronze and a double webbed crank, as shown in the sectional sketch. The air pump crankshaft is provided with four serrations which fit into the corresponding splines cut on the inside of the hollow camshaft. The bore of the pump is 40 mm., and the stroke is 40 mm.

Air inlet ports are drilled in the lower portion of the pump barrel and are uncovered by the piston at the bottom of its stroke, and the delivery check valve is situated in the head of the pump barrel. A regulating valve is provided directly above the check-valve, the released air escaping through the center of the hollow adjusting screw, and also through six small holes drilled radially in the threaded cap which forms the seating of the regulating valve.

A self-contained oil trap is provided by the gun-metal jacket which surrounds the barrel of the air pump. This is fitted with a drain cock, as shown in the sketch. The air pump piston and crankshaft are lubricated by the excess oil in the camshaft casing.

#### Details of Oiling System

The main oil lead from the oil pump to the hollow camshaft is taken through a passage drilled in the crank-chamber of the air pump, the oil entering the camshaft through four 5 mm. holes drilled radially in the hollow air pump crankshaft, which register with a groove cut in the inside of its bearing.

The following is a summary of a report of the 180-hp. Mercedes engine carried out at the Royal Aircraft Factory, Feb. 6, 1918:

The engine was erected on test bed, and coupled to a Heenan and Froude dynamotor, and power readings taken at various speeds, simultaneous fuel and oil consumption readings being taken. The results of these tests are shown graphically on the curves attached to this report.

These curves show the following readings:

R.p.m.	1300	1500
B.h.p.	165	180
B.m.e.p.	112	105.5
Fuel consumption in pints per b.h.p. hour.	.540	.555
Normal engine speed	1,400 r.p.m.	
Average b.h.p.	174	
Average petrol consumption	.545 pint per b.h.p. hr.	
Average oil consumption	.042 pint per b.h.p. hr.	

During a previous test the engine was run up to 1700

Above—Valve lift diagram. Left—Power, brake mean effective pressure and fuel consumption curves

r.p.m., at which speed 197.5 b.h.p. was recorded, but at this speed the engine was found to be incapable of giving constant power.

The engine was run at 1400 r.p.m. for the purpose of calibrating the output of the water pump, which delivered into a graduated tank at the rate of 41.4 gal. per min.

Owing to the fact that during the above test it was found to be impossible to tune up the engine, the power developed does not probably represent its best performance, as from other data and tests of the engine a normal b.h.p. of 179.5 at 1400 r.p.m. and a maximum b.h.p. of 188 at 1500 r.p.m. has been recorded.

Further details of the 180-hp. engine are given in the accompanying list of particulars.

Weights		Lb.
Weight of engine complete, dry, including propeller hub and exhaust manifold		660.0
Weight per b.h.p.		3.79
Weight of exhaust manifold		13.0
Weight of oil carried in engine		19.125
Weight of fuel and oil per hour		93.53
Gross weight of engine in running order, less fuel, oil and tanks, but including cooling system, at 0.64 lb. per b.h.p.		773.0
Weight per b.h.p.		4.44
Gross weight of engine in running order, with fuel, oil and tanks for six hours. (Tanks at 10 per cent weight of fuel and oil)		1,390.3
Weight per b.h.p.		8.00

#### Engine Data

Number and arrangement of cylinders	Six vertical, separate.
Bore	140 mm. = 5.51 ins.
Stroke	160 mm. = 6.30 ins.
Stroke-bore ratio	1.142:1.
Area of one piston	23.84 sq. ins. = 153.9 sq. c.
Total piston area of engine	143.04 sq. ins. = 924 sq. c.
Stroke volume of one cylinder	150.28 cu. ins. = 2.463 c.c.
Total stroke volume of engine	901.68 cu. ins. = 14.778 c.c.
Volume of clearance space	41.3 cu. ins. = 676.64 c.c.
Compression ratio. Total volume—clearance volume	4.64:1.
Normal b.h.p. and speed	174 b.h.p. at 1,400 r.p.m.
Piston speed	1,470 ft. per min.
Brake mean pressure	109.1 lbs. sq. in.
Cu. ins. of stroke volume per b.h.p.	5.18 cu. ins.
Sq. in. of piston area per b.h.p.	0.823 sq. in.

B.h.p. per cu. ft. of stroke volume. 334.0.  
B.n.p. per sq. ft. of piston area. 175.0.  
Direction of rotation of crank and propeller. Anti-clockwise facing propeller.  
Lubrication system. Forced, multiple plunger pump.  
Oil consumption per hour. 7.3 pints = 8.21 lbs.  
Oil consumption per b.h.p. hour. 0.642 pint = 0.047 lb.  
Oil pressure. 20 lbs. sq. in.  
Volume of oil carried in base-chamber. 17 pints.  
Number and type of carburetor. One dual Mercedes, twin-jet.  
Diameter of chokes. 0.945 in. = 24 mm.  
Bore of main jets. 0.058 in. = 1.472 mm.  
Bore of pilot jets. 0.022 in. = 0.559 mm.  
Fuel consumption per hour. 94.83 pints = 85.32 lbs.  
Fuel consumption per b.h.p. hour. 0.545 pint = 0.491 lb.  
Inside diameter of induction pipes. 2.126 ins. = 54 mm.  
Number and type of magnetos. Two, Bosch, Z.L.6.  
Firing sequence of engine. 1, 5, 3, 6, 2, 4.  
Ignition timing (fully advanced). 30° early.  
Speed of magnetos. 1.5 engine speed.  
Inlet valve opens. Top dead center.  
Inlet valve closes. 40° late.  
Diameter of inlet valve (smallest diam.) = d. 2.677 ins. = 68 mm.  
Lift of inlet valve = h. 0.453 in. = 11.5 mm.  
Area of inlet valve opening (w.d.h.). 3.81 sq. ins. = 24.58 sq. c.  
Mean gas velocity through inlet valve. 153.4 ft. per sec.  
Clearance of inlet tappet. 0.017 in. = 0.432 mm.  
Exhaust valve opens. 40° early.  
Exhaust valve closes. 10° late.  
Diameter of exhaust valve (smallest diam.) = d. 2.677 in. = 68 mm.  
Lift of exhaust valve = h. 0.453 in. = 11.5 mm.  
Area of exhaust valve opening (w.d.h.). 3.81 sq. ins. = 24.58 sq. c.  
Clearance of exhaust tappet. 0.014 in. = 0.355 mm.  
Diameter of inlet and exhaust ports. 2.165 ins. = 55 mm.  
Diameter of water pump inlet. 1.692 ins. = 43 mm.  
Diameter of water pump outlet. 1.575 ins. = 40 mm.  
Ratio of water pump speed to crankshaft speed. 1.5:1.  
Delivery of water pump at normal speed. 41.4 gals. per min.  
Inlet water temperature. 64° Cent.  
Outlet water temperature. 74° Cent.  
Water jacket capacity of one cylinder. 1,280 c.c.

Description of Part	No. per set	Average unit weight	Weight of complete set	Percentage of total weight
Cylinders (bare)	6	19.25	115.50	17.5
Pistons, complete with rings and gudgeon pins	6	6.85	41.10	6.23
Connecting rods, with gudgeon pin bushes	6	5.00	30.00	4.55

AN item in a recent issue of U. S. Commerce Reports deals with the subject of the manufacture of alcohol from the sotol plant. This plant grows in Mexico, and its supply is practically unlimited. It is stated that so far only about 100 bbl. of alcohol has been manufactured from the plant. That the manufacture has not been pushed to a larger scale is due partly to difficulty in securing competent distillery men and partly to the fact that the sap of the sotol plant has not the proper chemical properties from about June 1 to Aug. 15. Arrangements are reported to have been made to secure a good distillery man and to begin work about Aug. 15, with the expectation of having the plant operate at full capacity from that time on.

# A New Method of Obtaining Brinell Hardness\*

An Impact Substituted for a Steady Pressure to Reduce the Time Required for Applying the Test—Method Consistently Accurate

By J. G. Ayers, Jr.

THE present types of Brinell machines generally follow the original Brinell principle of forcing a ball of standard diameter into the steel under test by means of a standard load hydraulically applied. Several seconds are required to bring the full load to bear upon the ball and test specimen, and several more are used in maintaining this pressure, according to approved practice.

Under laboratory conditions, where time is not so important a factor as accuracy, the present types of machines are entirely satisfactory. There are cases, however, where testing must be done on a large commercial scale, as in the acceptance of raw material, and where the hardness range permissible does not require tests of laboratory accuracy. In such cases the rapid and approximate determination of the hardness of thousands of pieces is more important and productive of better results than the extremely accurate testing of a limited number whose hardness, unfortunately, is not always representative of the lot as a whole.

With the idea of overcoming this objection and of making possibly a simpler machine which, while not possessing the accuracy of the ordinary Brinell machine, would be capable of giving results that would be satisfactory for tests on a commercial scale, the writer has conducted experiments which have led to results far more encouraging than he had hoped. While the final form of the machine, including the necessary mechanical details, has not yet been developed, a description of the principle involved and the results obtained in the various experimental tests may prove of interest.

Instead of applying a standard dead load as in the ordinary Brinell machine, a given or standard impact was

Fig. 1—Cylindrical weight and 10 mm. ball

Fig. 2—Ayers-Brinell diameters plotted against standard Brinell hardness

used. It is of course impossible to choose a standard impact that will produce the equivalent Brinell impression in a steel of any hardness, but for a given Brinell hardness it is possible to determine empirically the impact required to produce an impression identical with the one produced by the

standard Brinell machine. It was decided to choose that impact which gives a 3-mm. diameter impression in a steel of 418 Brinell hardness. This impact would therefore give the same result on a steel of this hardness as the standard Brinell machine using a 10-mm. ball and a 3000-kg. load. A cylindrical 10-kg. weight with a cone-shaped lower end was used, in which the standard 10-mm. ball was fastened securely. See Fig. 1. The proper height from which the

weight should fall to produce a 3-mm. diameter impression was determined experimentally by raising it to various heights by means of a supporting wire and hand crank and then severing the wire. This height was found to be 70 mm., and the impact would therefore be 0.700 m.-kg. Using this impact as a standard, specimens of various Brinell hardness were tested by this device and the diameters of the impressions obtained were plotted as ordinates against the standard Brinell machine hardness numbers as abscissas. Fig. 2 shows the results obtained.

As it is sometimes advisable to use a lighter load than 3000 kg. with the standard Brinell machine, it was decided also to try the effect of a lesser impact. Instead of taking one-half the standard impact of 0.700 m.-kg., that height of fall was determined which would give a 3-mm. diameter impression in a steel of 209 Brinell hardness using the same 10-kg. weight and 10-mm. ball. In other words, the new device would give the same result on a steel of this hardness as the standard Brinell machine using a 10-mm. ball and 1500-kg. load. This height was found to be 36 mm., giving an impact of 0.360 m.-kg.

In Fig. 2 the hardness-impression curve is practically a straight line and the points experimentally determined fall as closely to this line as could be desired, considering that in no case does their deviation from the line amount to a greater distance than that corresponding to the error involved in the microscopical determination of the diameter of the impression. Repeated tests gave excellent checks in all cases and showed that this method is consistently accurate and free from erratic tendencies. Each determination can be read directly in standard Brinell numbers by the use of Table I, the data for which has been obtained from Fig. 2.

\*Paper presented to the American Society for Testing Materials at its annual meeting at Atlantic City, June 25-28, 1918.

# Grant Company Making Three Ordnance Trailers

Types Adapted for Use as Cargo Carriers, Gun Platforms and Shops—Incorporate Standard Features Where Possible

*Ten-ton trailer loaded with a small French tank*

THE line of trailers manufactured for the Ordnance Department by the Grant Motor Car Co., Cleveland, clearly illustrates the great variety of uses to which trailer equipment can be put in warfare. There are three of these trailers, one for moving 3-in. field guns and which is also adaptable to the French 75, or the equivalent English field piece; another, a 4-ton trailer upon which may be mounted a shop body, a cargo carrying body or a variety of other bodies, and the third a trailer for anti-aircraft guns which forms a platform for the gun and upon which the gun is mounted permanently.

The 3-in. field gun trailer has a capacity of 9000 lb. It has a wheelbase of 120 in. and a track width of 77½ in. By its use the mobility of the U. S. 3-in. field piece, or the French and British equivalent, is greatly increased, since this trailer with the gun can be towed behind a tractor or truck at a much higher speed than would otherwise be possible.

The trailer is a four-wheel type having a single-end steer, the steering being accomplished through the drawbar by means of a flexible connection with the steering lever, which is in turn connected to the steering cross-arm. The trailer is built on a pressed steel frame, mounted on semi-elliptic springs on the I-beam front axle and the rectangular dead rear axle. The floor is of oak planks carried on wood bolsters with mountings to support it at the required height above the frame cross members. An inverted panel is provided along the center of the floor and there are four recesses to leave clearance for the gun trail. To provide for the different guns to which this trailer can be adapted, there are three special pintles which can be mounted at the desired points along the platform.

The front axle is an I-beam section to which is bracketed a central supporting member to carry the steering lever. Pivoted to the steering lever on the center line of the trailer are the two steering cross-arms. These connect in turn with the steering knuckles and are laid out so that the trailer will

track accurately behind the tractor which tows it. The front wheels are roller bearing mounted.

The rear axle is a rectangular section forging, carrying the rear axle spindle as an integral unit. Roller bearings are fitted to these spindles to support the load of the rear wheels. The rear axle is a dead member and is dropped just inside the spindle, allowing the semi-elliptic springs to be overslung. The rear wheels carry the brake drums in which operate the internal expanding brake shoes, which are controlled by a hand lever at the front end of the trailer. The brake drums are 19 in. in diameter and the shoes are faced with asbestos fabric. Brake action is controlled by a straight pull rod from the hand lever at the front end of the trailer. There is a ratchet on this lever which allows the brake to be locked on in case it is desired.

The drawbar has a double coil spring housed within it, which takes up the towing shock in either direction. The drawbar is 42 in. in length and connects with the steering lever by means of a pin yoke which allows the drawbar eye to be raised or lowered in engaging it with the pintle on the tractor. On the rear end of the trailer the standard pintle is fitted, which permits towing.

For loading the trailer two channels are provided which hook on the rear end, giving a ramp up which the guns can be hauled. These channels are detachable and are carried on the trailer frame when not in use.

The springs are interchangeable front and rear, being 42 in. long and 3 in. wide. The wheels are cast steel 36 by 6 in., adapted for demountable tires. There are eight spoke wheels and the tire fastenings are so arranged that the tires will be interchangeable with those used on the Nash and F. W. D. trucks. Throughout this trailer is designed to be interchangeable with the trailer used for the 3-in. anti-aircraft gun, in so far as similar products are employed.

For mounting the 3-in. anti-aircraft gun a trailer of 10,000-lb. capacity is provided. This trailer is a four-wheel

type, mounted on a wheelbase of 156 in. The frame is of pressed steel, spring supported on the front and rear axle and dropped for most of its length below the level of the supporting members at the axle. On the pressed steel frame is mounted a base plate suitable for attaching the gun to it, and the front and rear ends of the platform are covered by a steel plate  $\frac{1}{2}$  in. thick, forming a platform for the gun crew to stand upon.

The front end steering mechanism is similar to that of the 3-in. field gun trailer just described. There is also, however, a rear end steer, controlled by a bar or pole at the rear end. The rear wheels are locked in position when this pole is not in use, and the pole is carried in special brackets along the side of the trailer. A locking device is provided which is so designed that the pole cannot be withdrawn unless the wheels are in the center position. After the pole is withdrawn the wheels cannot be steered until it is re-inserted.

#### Front and Rear Axles Similar

The front axle is an I-beam section similar to that of the field gun trailer, and the front axle is dropped and carries the semi-elliptic spring overslung. The rear axle is similar in a great many respects to the front, being also a dropped I-beam section, with the same semi-elliptic springs overslung. The rear steering knuckles are forged and the spindles carry roller bearings which support the wheel load, as in the case of the front wheels. The brake drum is pressed steel, bolted to the rear wheels, in which the internal expanding brake operates. This brake is mounted on a 16-in. gun capable of holding the loaded trailer on a 20 per cent grade. The brakes are operated by a hand lever at the rear right hand side of the trailer. A seat and suitable foot rests are provided for the man operating the brakes. The frame on this trailer is 8 in. deep and is formed from  $\frac{1}{2}$ -in. stock. It is braced at the rear end to take the Ordnance Department standard pintle and to allow for towing of another trailer of the same size as that described herewith.

In addition to the trailers described, the Grant Motor Car Co. is also making a 4-ton trailer suitable for carrying a number of bodies such as a repair shop, a cargo carrying body and other equipment. This is also a four-wheel type with single end steer. The drawbar connection is similar to the trailers described previously. The trailer is built upon a frame of standard 8 in. by 13 $\frac{1}{4}$  in. commercial steel, with channel side rails and front and rear cross rails. This framework is substantially reinforced by cross members of channel and I sections.

The wheelbase of the trailer is 156 in.; the track width, 72

in.; the frame length, 19 ft. 4 in., and the frame width, 44 in. overall. The axles are carbon steel forgings.

The front axle is a drop-forged I-beam section to which is bracketed a central supporting member carrying the steering lever. Pivoted to the steering lever on the center line of the trailer are two cross-arms, these connecting in turn with the steering knuckles and being so arranged that the trailer will track accurately behind the tractor which pulls it. The steering knuckles are drop forged and are the straight Elliott type. The wheels are mounted on roller bearings.

The rear axle is rectangular in section and is drop forged from carbon steel. The axles are 4 in. deep by 2 $\frac{1}{4}$  in. wide. As the rear axle is a dead member, the spindles are forged integrally with it and carry the wheels on roller bearings. The rear wheels carry the brake drums, in which operate the internal expanding brake shoes, which are controlled by a hand lever mounted at the front end of the trailer. The brake drums are 19 in. in diameter and the shoes are faced with asbestos fabric. The brake linkage is controlled by a straight pull rod from the hand lever. There is a ratchet on this lever which allows the brake to be locked.

The drawbar is a standard type, having a double coil spring housed within it. The drawbar is equipped with a spring mounted eye or lunette of 3 in. diameter and 6 in. outside diameter. Attached to the rear end of the trailer is the standard Ordnance type of pintle.

The springs are interchangeable and have main leaves of chrome vanadium steel. The other leaves are of carbon steel. The springs have an eye at one end and an arc at the other which rests over the rear spring mounting in such a way that the spring is free to slip over it when it lengthens, due to reflection. The length is 48 in. from the center of the eye to the center of the rear arc. The width is 4 in., the main leaf  $\frac{3}{8}$  in. thick, and the other leaves are 5/16 in. thick. The springs are held by two clips and the eyed ends are fitted with bushings of the proper size to take a 1-in. spring bolt.

The height from the top of the ground to the top of the frame when the trailer is fully loaded is 31 in. The live load on the trailer approximates 6600 lb. and the dead load totals 4400 lb. The tires are 36 by 6 in., pressed on, and the painting is in accordance with the standard camouflage specifications.

AS an extension of its factory betterment work, the New Departure Co. of Bristol, Conn., is installing shower baths for the men engaged in the hardening shop and other so-called hot departments.

# Thermostatic Generator Control Now Proved Success

Compensation for Atmospheric Temperature Found  
by Remy to Result in Saving of Battery Life

**C**ARS equipped with the Remy thermostatically controlled generator have been on the road for about 18 months. This has given ample opportunity to observe the success of thermostatic control for automobile starting and lighting systems. The result has been found by the Remy company to be beneficial to battery life and the thermostat controlled generator is now used as standard equipment on the Harroun, Kissel, McLaughlin, Mitchell, Oakland, Olds, Paige, Reo, Scripps-Booth, Stanley Steamer, Templar, Velie, Atlas truck and Grant Denmo trucks.

The advantage of thermostatic control is based upon the fact that it requires more current for lights and for the starting motor in winter than in summer. The result of this is that the storage battery is more apt to be found in a drained condition during the winter months than in the summer. To meet this variation in demand for current, the Remy generator has been equipped for some time with the thermostatic control, which automatically reduces the generator output in summer time and increases it in winter.

The diagram, Fig. 1, shows the mechanical construction of the thermostat. A stamped steel bracket carries a resistance unit, a silver contact point and a thermal blade, insulated from the bracket and carrying a second silver contact point. The contact point in the thermal blade is held against the similar contact in the bracket, by the spring tension of the blade itself, at low temperatures. The blade is, however, made of a strip of spring brass welded to a strip of nickel steel, a combination which warps when heated, due to the greater expansion of the brass. The contacts are thus separated by the bending of the blade whenever the thermostat is heated to approximately 175 deg. Fahr.

It will be seen from Fig. 2 that when the thermostat is closed the field current takes the low resistance path through the contact points, but when the thermostat is open the field current is forced to go through the resistance unit. By this automatic insertion of resistance in the field circuit the generator output is reduced to a predetermined value. The operation of the thermostat

Fig. 3—Output curves with thermostat open and closed respectively

is illustrated in Fig. 3. The generator output is 21 or 22 amperes after starting with a cold machine, and with atmospheric temperatures around 70 deg. the thermostat will open after 2 or 3 miles, which is sufficient time to make up the amount of energy taken from the battery in starting. When the thermostat opens the output will drop to 14 or 15 amperes at average driving speed. In very hot weather the thermostat will open much quicker. In extremely cold weather the thermostat will remain closed, insuring the continuous high generator output needed to meet the increased demand made by the starting motor and the increased burning of lights.

In addition to correcting the difference between winter and summer demands for current, the thermostat control makes it possible to keep the battery fully charged under unfavorable conditions, such as an exceedingly large number of starts, and the use of the car for a large percentage of night driving. The thermostatic control is supplementary to the third-brush regulation which is set to keep the charge rate from rising above the predetermined maximum of 20 to 22 amperes for a cold generator when the car is operated above the average driving speed.

Fig. 2—Circuit diagram of Remy third brush control system with thermostat

# Two New Demountable Motorcycle Wheels

In One the Driving Hub Is Driven by Pins in the Flange of Combined Chain Sprocket and Brake Drum—In the Other the Drive Is Through Hookham Joints

*Comery demountable motorcycle wheel*

*Lechmere demountable wheel, driven through a Hookham joint*

**P**ATENTS have recently been issued by the British Patent Office on two designs of demountable wheels for motorcycles. The first of these is in the name of W. Comery, who is connected with the Raleigh Cycle Company of Nottingham. Mr. Comery forms the hub proper *E* as a separate fitting, which is mounted upon a hollow sleeve-like spindle *A*, the usual ball or roller bearings being interposed. The wheel is provided with a tubular, shell-like center *F* which is flanged on the outside to receive spokes *H* and is adapted to fit on to the hub *E*, an inclined projecting rim *J* on the latter engaging one end of the wheel center.

The sprocket wheel *B* is centered on a member *P*, secured to the frame, and is provided with an inclined surface *M*, adapted to engage with the adjacent end of the wheel center *F*, inter-engaging screw threads being provided on the driving element *L* and hub proper *E* to secure the same together, with the wheel center wedged between the two. When so connected, the driving element, wheel and hub are firmly locked together, projection *O* on one member entering recesses in the other. The member *P* secured to the frame is bored to correspond with the hub spindle, and a short sleeve or spacer *S* is correspondingly bored to complete the distance between the sides of the frame *R*, a removable bolt *T* being threaded through the three members and the side frame to secure them together, with the wheel in the correct position. The bolt may be bored and one end enlarged to form a lubricant reservoir, transverse holes being formed in the bolt and hub spindle to allow lubricant to be forced into the hub. When it is desired to remove the wheel, the two bolt *T* is withdrawn, the short spacer *S* removed, and the hub *E* is then disconnected from the driving element *L* which is left centered on the member *P* attached to the frame, the wheel and hub being removed bodily and then slid apart.

The other demountable wheel is patented by W. F. Lechmere of the James Cycle Co. of Birmingham. This bears considerable resemblance to the demountable wheel used on the U. S. A. motorcycle, in that the whole wheel construction is in three parts, which are fitted together by tongues and grooves. The sprocket wheel *A* is rotatively mounted upon a sleeve secured to the frame, and the brake drum *B* is rotatively mounted upon another sleeve secured to the opposite

side of the frame, while the hub *C* is disposed between the sprocket wheel and the brake drum. Mutual engaging projections and recesses are formed on the outer spaces of the hub and the inner spaces of the sprocket wheel and brake drum, and a detachable, non-rotatable spindle passes through the hub and sleeves. Each end of the hub is provided with a diametrically disposed projection *D*, which is adapted to engage with the correspondingly shaped recess *E* in the sprocket, and a similar recess *S* in the brake drum. The hub is secured in position by means of a detachable spindle *G*.

## Cellulose Acetate Dope

**C**ELLULOSE acetate is the principal ingredient in dope for Caeroplan wings, requiring for that purpose to be mixed with certain solvents. It is also used in film form for windshields for aeroplanes, etc., its main value for both these purposes lying in its non-inflammable character. It is employed for a vast number of peace time products, and by-products in its manufacture are of importance, both in war time and peace. In the manufacture of cellulose acetate the principal ingredients are paper or pulp and acetic anhydride.

## A New Type of Link Chain

**A** NEW type of chain made up of weldless links is being announced by the Cleveland Galvanizing Works Co. Hodell chain is made of flattened wire in a machine which, it is claimed, automatically rejects any wire which is imperfect. This machine loops the wire, bends it and laps the ends in such a way that the next link cannot drop back and wedge, as happens in ordinary flat chains. This, and the smoothly rounded contacts, due to the use of smooth drawn wire, give what is referred to as a roller bearing effect. The chain is claimed to be very flexible and free from any tendency to buckle and kink. A feature of value in the Hodell chain is the double thickness of the eye where the wear is greatest, and the reinforcement there which prevents the chain from flattening and lengthening under strain.

# The Pfalz Single-Seater Fighter\*

## Part II

### Mounting of Tail Plane, Tail Skid, Vertical Fin and Rudder and Construction of These Parts

**A**T the stern the Pfalz body terminates, as shown in the illustrations, in a somewhat elaborate framework of wood, which performs the various functions of forming supports for the tail plane, tail skid, and vertical fin with its rudder. The second former from the stern is, it will be seen, sloped backward to form the leading edge of the vertical fin, and is reinforced above the body with other pieces of wood to give it a rounded edge. The last former is in duplicate, its front half extending upward to form a member of the fin, while the other half terminates just above the body and serves chiefly as a support for the short length of spar to which the front spar of the tail plane is attached. Between these two formers, and sloping so as to form in side view a cross, are two other formers, built up in much the same manner as the main body formers. The angle formed by one of these and the longeron accommodates the leading edge of the small plane permanently fixed to the body, while the point of intersection of the two formers supports a short

transverse cylindrical piece of wood, around which are wrapped the shock absorbers for the tail skid. The details of both these joints are shown in the sketches. The small tail plane root is covered with plywood.

The tail plane itself is in one piece, and fits into the slot provided for it in the body. The manner in which it is secured after being placed in its slot will be clear from an inspection of the tail plane drawing. The front spar rests in the slot in the body, and is secured against lateral tilting by a steel band on each side, overlapping the butt joint between the front part of the rib and the tail plane root. The rear spar of the tail plane is locked in place by two long bolts and a stud. The two bolts are placed one on each side of the stern, as indicated in the sketch, while the stud passes through a lug welded on to the extreme rear of the steel shoe surrounding the heel of the fuselage into another lug near the foot of the stern post. The whole tail plane with its elevator can therefore be removed by undoing five nuts, and, of course, the connections in the elevator control cables.

\*From *Flight*.

#### Tail Plane and Elevator

As regards the tail plane and elevator themselves, these are constructed along more or less standard lines and do not present any especially remarkable features. It has already been pointed out that the tail plane appears at first sight to have been put on "upside down," having a flat top surface and a convex bottom surface. The reason for this is not apparent, but it is possible that the disposition of the various weights and surfaces is such that there is either a lift-weight couple or a thrust-resistance couple or both, and that this section tail plane has been employed to equalize such couples. However, in a later machine captured and now at the Enemy Aircraft View Rooms the shape of the tail plane has been altered to a symmetrical section, so that it would appear that the "inverted" section has either been found unsatisfactory in practice or the reasons for its employment removed in a later design. Structurally the tail plane is built up of spruce spars with ribs having ash flanges and poplar webs. The inner ribs are covered with three-ply to give extra rigidity for attachment to the body. The front spar is of I section, while the rear spar is channel section, with recesses top and bottom for forming a flat surface with the rib flanges. There is no internal wire bracing, the necessary rigidity being obtained by means of diagonal ribs and by plates of three-ply placed over the joints between ribs and spars. The leading edge, which is also bent back to form the tips of the tail plane, is laminated as shown, and is lightened by spindling between the ribs. The laminations are probably steamed so as to be easily bent to form the rounded corners of the tail plane.

The elevator, owing to the fact that the rudder has no downward projection, is in one piece, and is built up in a manner similar to that of the tail plane. Its leading edge is formed by a box spar, and the ribs are similar to those of the tail plane. The attachment of the ribs to the trailing edge is somewhat unusual. Instead of the flanges of

Framework of the stern

Steel tubular frame of rudder and rudder hinge

the ribs passing over the trailing edge they are thinned down and pass into a slot in the trailing edge. They are then secured in place by a small metal clip. The slots in the trailing edge appear to have been made with a circular cutter of about 3 in diameter, the ends of the rib flanges being placed where the slot is deepest. The ele-

vator hinges are formed by forked bolts passing through the rear spar of the tail plane, and corresponding with eye bolts through the leading edge of the elevator.

The elevator crank levers are of a type frequently found on German machines. The crank itself is of stream-line section and is welded to a channel section base plate surrounding three sides of the leading edge. Another base plate of similar shape, but made of lighter gage, is slipped over the leading edge from the front and forms a washer for the hinge bolt, which passes through the leading edge at a point coincident with the crank lever. The attachment of the elevator and rudder cables to their respective cranks is in the form of a ball and socket joint, or, more correctly speaking, the ball portion of it is not a complete ball but a slice of a sphere, formed integrally with the bolt passing out of the socket into the barrel of the wire strainer. The socket, and also the ball, have a flat formed on one side so as to prevent the ball from turning in the socket. Behind the ball a small split-pin passes transversely through the socket, thus preventing the ball from dropping out of the socket when the control cables are removed. The socket is kept filled with grease.

The rudder, which, as already pointed out, is placed wholly above the elevator, is built entirely of steel tubing. The ribs are joined, not directly to the rudder post, but to a collar of very light gage, which is in turn pinned and braced to the rudder post. The object of this construction probably is to avoid weakening the rudder post by welding, since all the rudder ribs can then be welded to their collars on a jig, the rudder post being inserted afterward and the collars pinned in place.

The rear end of the ribs is joined direct to the trailing edge by welding. The method of tapering the rib tubes down toward the trailing edge is different from anything we have yet seen on a German machine. A vertical slice is taken out of one of the tubes, and the edges thus formed are pushed over the other tube of the rib, the two tubes being held together by short welds at intervals.

The foot of the rudder post rests in a cup or shoe on the trailing edge of the vertical fin, while additional hinges are provided at intervals. To prevent the rudder post from sliding up and down a collar is placed above and one below each hinge. To these collars are welded two U-shaped rods around which is wrapped fabric in order to form an airtight joint at the points where the hinge pierces the rudder covering. In the illustration the fabric wrapping has been omitted for the sake of clearness.

The tail skid is of somewhat unusual shape, as shown in the right-hand sketch. Owing to the fact that there is no vertical fin below the body of the Pfalz, and no downward projection of the rudder, it has been possible to reduce the head resistance of the skid by making it horizontal for the greater part of its length, with just a downward curve at the rear to give greater clearance for the tail plane. The skid is pivoted on a bolt passing through a lug on the heel of the fuselage. Its free end is sprung by rubber cord from the short cylindrical piece of wood already referred to. This attachment looks remarkably weak—a piece of wood, slotted at its ends to fit over the cross formed by the two sloping body formers. Yet in all the captured specimens of Pfalz machines that we have had an opportunity to examine, this particular member has never been broken. As to the skid itself, it is built up of ten laminations of wood, each about 5 mm. thick. At the rear the skid is provided with a sheet metal shoe to protect it against wear.

### Problems of Propeller Design—Propellers with Adjustable Pitch—Stability and Control—Armament and Instruments

By Dr. W. F. Durand

WE shall now turn our attention for a few moments to one of the most intricate and hence one of the most interesting of the many problems presented to us by the aeronautic art, that of the airscrew or propeller.

The function of the airscrew is, of course, to take the torque of the engine and to transform it into a propulsive thrust; or otherwise to take the power given by the engine to the crankshaft and transform it into driving or propulsive power for the aeroplane. The problem is further complicated by the fact that expressed in terms of a power relation, it is not simply the question of an engine handing so much power over to the airscrew for the latter to transform into propulsive power. Instead, the power which the engine itself can develop is dependent on the propeller and likewise on the aeroplane to which they are both attached. We have here, in consequence, a series of complicated implicit relations, and from which the propulsive characteristics of the plane-propeller-engine combination take their origin. In fact, it must never for a moment be forgotten that the moving aeroplane is in effect an aeroplane-motor-propeller combination and that no one of the three can be determined independent of the other two.

#### Influence of Airscrew

Without entering into any detailed discussion of this problem, it will be clear that the airscrew will exercise a controlling influence on the power which the engine can develop. Thus, it is evident that an aeronautic engine, in order to develop power, must be permitted to move its pistons, to revolve its crankshaft; in other words, to make revolutions; and other things equal, the power developed will vary directly with the revolutions which are realized. Again, it is easy to see that the size and amount of surface of the airscrew blades will present a controlling feature regarding the revolutions which can be realized. Thus, the airscrew may be enormously over size, too large in diameter and presenting a large and unwieldy surface to the air. Suppose this to be the case with a plane of size suited to the airscrew but not to the engine. That is, the engine is far too small for either airscrew or plane. In such case the engine simply will not be able to make its normal number of revolutions. It will be held down by the excessive resistance to rotation presented under such circumstances, and may thus develop far less than the normal power which it is capable of under proper conditions. Many other combinations may occur which we cannot stop to discuss or even to mention. Broadly speaking, the plane, the engine and the airscrew, as the propelling agent, form a most closely knit combination and each interacts in a more or less controlling manner on the operation of the other two.

In order even to make a start with the problem of the airscrew it is therefore necessary to assume conditions regarding both the plane and the engine. If these conditions,

as assumed, are then realized in practice and if the design has been well carried out, the anticipated results may be reached. If, on the other hand, the assumed conditions are not realized as regards the plane and the engine, then no matter how well the design of the airscrew may have been carried out, the anticipated results will not be realized. Hence, no matter how good the airscrew may be by itself, no matter how carefully designed and constructed, no matter how faithfully it may be able to realize the conditions for which it is designed, if these are not the conditions under which it is actually placed for service, the results, economic and otherwise, will be unsatisfactory; not necessarily by reason of any fault in the airscrew as such, but due simply to its lack of adaptation to the conditions of operation. An effective airscrew is therefore not only one which is properly designed and constructed in itself, but also one which is permitted to operate under the conditions intended and contemplated in its design.

All this is, of course, well known, and if I have taken the time to repeat these well-known facts, it is the more clearly to bring to our minds at the present moment the fact that the airscrew represents not only a problem in itself, but also one of adaptation to and of usage with the proper combination of plane and of prime mover.

The general problem of the airscrew is by no means, however, to be classed distinctively as outstanding. Instead, an enormous amount of work has been done on it, both theoretically and experimentally, and in its main features it has been brought fairly within the limits of a solved problem. There have been three modes of approach, briefly, as follows:

#### Three Methods of Treatment

(1) The analysis, geometrically, of the blade of an airscrew into a series of elements, occupying each a narrow strip running across the blade from leading to following edge and making up, by their summation, the blade as a whole. Each of these elements or strips is then considered as, in effect, a little elementary aerofoil and for which the usual aerodynamic characteristics are readily determined, either by direct experiment on a model, or by selection or interpolation from and among the large amount of available data regarding such aerofoils which have already been submitted to experimental investigation. With such data in hand relating to the series of elements going to make up the blade, it is a matter of simple computation to combine them in such manner as to represent the action of the blade as a whole, under the conditions assumed, and thus in general terms the problem is solved.

(2) A law of similitude is assumed and a small model propeller is tested out experimentally and under conditions which permit, under the law of similitude assumed, the translation of the *observed* results for the model into the *probable* results for the full sized airscrew.

(3) Full sized airscrews are tested out as nearly as may be under flying conditions and are made the ultimate basis of design.

\*Sixth Wilbur Wright lecture read before the Aeronautical Society of Great Britain at London, June 25.

The limitations of method No. 1 arise from the following:

(a) The coefficients derived for aerofoils correspond to straight line motion between the air and the foil, whereas, in the airscrew, the relative motion is in a helical or spiral path.

(b) The actual velocities for which such coefficients are derived are usually for speeds not exceeding 60 or 70 miles per hour, whereas the actual speeds of the tip elements of airscrew blades may move at speeds of 500 m.p.h. and upward. The extent to which the usual square of the speed law may be extended to such values is not as yet fully known.

(c) The coefficients used are derived for the various aerofoil sections or elements individually, whereas, in the actual airscrew, they all act conjointly or collectively in making up the airscrew blade.

#### Application of the Three Methods

Application of method No. 1 cannot therefore be made except in so far as it is justified by actual and final experience on full sized forms under flying conditions.

Method No. 2 (that with reduced size models) has the limitation that the law of similitude employed is, of necessity, not exact but approximate, and the degree of reliance which can be placed on results thus found can again only be determined by ultimate reference to full sized forms under flying conditions.

Method No. 3 (that with full sized forms under actual flying conditions) has the limitation of very high cost, both in equipment and time, and as a result of which only a relatively small number of forms can actually be subjected to adequate test in this manner.

Again, method No. 1 (that of computation based on coefficients determined by laboratory experiment) has the advantage of requiring only a pencil and pad of paper with a table of predetermined coefficients. No. 2 (that with the small models) has the advantage over No. 3 of relatively small cost, of permitting the tests to be carried out in a wind tunnel with all conditions under control, and finally it permits of carrying quickly through the test program a very large number of types and forms. It should perhaps be stated here that as between methods No. 1 and No. 2 the latter is accepted as much the more reliable of the two. In fact, it is not too much to say that when used with judgment it furnishes a very satisfactory and well-nigh universally accepted method for dealing in a laboratory way with most problems of airscrew design and operation.

#### Parts of Problem Still Unsolved

If we have tarried so long over these phases of the problem of the airscrew propeller, present methods of design, etc., it is in order to bring into clearer relief the parts of the problem which are not yet well in hand—the parts which are as yet outstanding and waiting our further study.

These phases which thus stand out represent in effect the lack of an adequate correlation between the three methods of approach as above described.

It is obvious that if we could develop an adequate and reliable correlation between the results of the computation according to method No. 1 and the final test under flying conditions according to No. 3—if, in other words, we could adequately determine the error of No. 1 and hence the correction to be applied in any given case, then a pencil and pad of paper would go a long way toward furnishing the material for the solution of the problem of airscrew design, once we are permitted, of course, to assume a definite set of operative conditions.

Or again, if we could know more accurately and more widely the character and amount of error to be anticipated in the use of the small models according to method No. 2, we should be in a position to use the experimented model method with better assurance of definite and reliable results for the full-sized screw later to be constructed.

It seems likely that this final correlation of computation with ultimate result may best be made in two stages. The first should comprise a careful study of the relation between the results derived by the computations of method No. 1 and the model tests of method No. 2. Such a correlation would then permit us to pass readily from the results by computation to the probable results by model.

The second correlation should then comprise a series of comparative tests to determine with sufficient generality of application the character and amount of correction to be applied to the results of model tests in order to satisfactorily reproduce the results to be expected from full-sized forms.

This would, by no means, require the testing of a full-sized form corresponding to each model. If so, there would, of course, be no use in making model tests. The whole program might as well be carried out directly by tests on full-sized forms. It appears reasonable to expect, however, that a well selected and not too numerous series of tests, properly distributed among the various characteristics of form and of operation, would serve adequately to give the correlation desired.

With such correlations established we should then have two methods, Nos. 1 and 2, available for the design of airscrews. No. 1 available with no more than a pencil and a pad of paper (once the standard section coefficients determined), and No. 2, by model, ready to supply a vast amount of detailed information regarding operation under varying conditions, and which may be realized rapidly and effectively once the model is made.

If we have spent so much time over these matters relating to the airscrew, it is because of its importance as an element in aerial navigation, and in order that we may the better note just what part of the general problem is still outstanding.

This, as we have seen, lies primarily in the matter of the correlation between the three methods outlined. There is indeed need for continuing experimental research, especially on systematically selected forms, both model and full size; and such continuing experimental work combined with carefully directed studies of correlation will go far toward giving us an assured and adequate basis for the practical solution of the airscrew problem as applied to aerial navigation.

#### Reaction Between Airscrew and Plane

Perhaps the widest and most important outstanding problem in connection with aeroplane propulsion has relation to the reaction between the plane and the propeller—the influence of the structures adjacent to the propeller on its performance, economic and otherwise, and the influence of the propeller on the plane, both as regards its lift and its net resistance to propulsion. This is a field which is largely outstanding. It must be attacked chiefly by the experimental method—by model with results checked up by comparison with full scale trials so far as practicable. Time forbids more than the mention of this promising and largely uncultivated field of aerodynamic investigation.

Of a closely related nature is the problem of the interaction of two or more airscrews on one shaft. This is a problem which is becoming of importance in connection with the increase in power of aeroplane power plants and with the fitting of more than one airscrew on the same shaft.

This likewise is a problem which must be approached experimentally—again through model research checked up by comparison with full scale tests. A beginning has been made on this important and interesting problem, and we may expect, in a not distant future, to find it brought within limits of control similar to those surrounding the problem of the individual airscrew.

#### Airscrew with Adjustable Pitch

In addition to these problems which relate to aeroplane propulsion in its general aspects, and more especially when for the sake of simplicity we assume that the aeroplane remains under a uniform regimen as regards external conditions, there arises a problem of very great present importance, that of some form of adjustment in the technical characteristics of the aeroplane—propeller combination permitting it to be made responsive to variations in the regimen of operation, as for example, change in the density of the air due to change in altitude, or change of regimen required for climbing flight as compared with horizontal flight.

In connection with the prime mover, mention was made of the very important problem of maintaining power at altitude in spite of the decrease in the density of the air. In reality this problem is very intimately bound up with another

of scarcely less importance, that of devising means for effectively using such power for propulsive purposes. Without attempting any technical discussion of the question, it will be apparent that the whole problem of the operation of the airscrew as a means for absorbing the power of the prime mover and converting it into the propulsion of the plane will depend on the density of the medium in which and on which it operates. Again, in climbing flight a part of the weight of the aeroplane is carried by the pull or thrust of the airscrew. In horizontal flight it is all borne by the planes (assuming the airscrew shaft then horizontal). Hence, the pull or thrust of an airscrew and indeed its whole regimen of operation may vary widely according as the plane is climbing or flying horizontally. It thus seems reasonable to conclude that for the best results there should be provided some mode of adjustment or compensation so that the airscrew, as it finds itself operating in a medium of continuously decreasing density, or as it finds itself called upon for varying amounts of thrust or pull with varying angles of climbing flight, may be correspondingly adjusted in order to give continuously the best results.

The problem is further complicated by the fact that the aeroplane itself needs a correlative adjustment. As we have already seen, the one factor in aerial flight which remains sensibly constant under all conditions and at all altitudes of flight is the weight of the plane and its equipment. The vertical supporting force gained from the reaction of the air must therefore be maintained constantly equal to this weight at least for the conditions of horizontal flight, while for climbing flight the weight will be divided and borne partly by the supporting planes and partly by the airscrew. The problem of the economic use of power at varying altitudes and under varying angles of climbing flight involves therefore the following chief elements:

#### Chief Elements Involved In Use of Power

- The weight of the plane.
- The surface of the wings and their aerodynamic characteristics.
- The angle of attack of the wings.
- The speed.
- The power developed by the engine.
- The revolutions of the airscrew.
- The area and form of the blades of the airscrew.
- The pitch of the airscrew.

These various factors react and interact in a most complex manner, and any attempt to discuss the problem in detail would carry us too far afield on the present occasion. Reference has already been made to the problem of wing surfaces, adjustable either in area or form. Such adjustments are, however, not yet available, and at present the angle of attack is the one feature about the plane which may readily be varied. On the other hand, there is no feature of the propulsive agent, the ordinary airscrew which admits of equally simple correlative variation. What is needed with regard to the airscrew is, indeed, some means of realizing an adjustment correlative to the change in the angle of attack for the plane. To this end a change of pitch is most suitable, some means of varying, at the will of the pilot, the pitch of the screw in order that with the fixed diameter and area of surface, and with the work available per revolution of the engine as affected by the density of the air, the pitch may be so adjusted as to secure the number of revolutions best adapted to the economic use of the power given out by the prime mover. This will then insure the thrust needed to overcome the resistance of the plane at the angle of attack and speed which, taken conjointly, will give the lifting force needed to support the weight of the plane, either in whole or in part, according as the plane is flying horizontally or climbing.

#### Two Problems Involved

All of this somewhat complicated statement means simply that what is wanted is an airscrew with blades adjustable for pitch. Such an airscrew may be realized by so pivoting the blades that they may be turned about a radial axis, thus changing their angle relative to the axis of the screw itself. Extreme changes of such a character result in a very wide variation of pitch from root to tip and in the end will

result in a serious loss in efficiency. There are therefore two problems involved:

(1) The aerodynamic problem of determining the best form and proportions of an airscrew, the blades of which are intended to be pivotable in this manner, so that under the widely changing conditions of flight which may be met with, there may be effective operation and a well sustained efficiency.

(2) The mechanical problem of so designing and building an airscrew with adjustable blades that it will meet the rigorous requirements imposed upon it by the exacting conditions of aeroplane navigation.

It is perhaps not too much to say that the first problem is already well in hand. We know reasonably well what forms and proportions to give to such an airscrew, and if it were only a matter of design or of the determination of form and proportion, the problem could hardly be called outstanding.

As much cannot be said regarding the second problem. The practical construction of an airscrew with adjustable blades is not an easy matter. Several modes of construction have been attempted, but with only moderate success. The problem is clearly defined, of the highest order of importance, and is outstanding as one of the appliances for which the art of aerial navigation is definitely in waiting.

#### Three Fundamental Requisites

The three fundamental requisites of an aeroplane are strength, movement and stability with control. We have noted some of the problems arising under the requirements of strength, and movement or propulsion. We may now turn very briefly to a glance at the situation regarding stability and control. Any detailed discussion of these problems would be quite out of the question on the present occasion, and time in any event will only allow us a brief glance at the general situation.

Regarding stability and control it is not too much to say that the general principles underlying these characteristics of an aeroplane are now reasonably well understood, due largely to the splendid theoretical and experimental investigations initiated by British scientists and to which certain workers in the same field in the United States may have contributed something, and by no means overlooking certain important contributions by French and Italian investigators. These investigations, both analytical and experimental, have placed the study of these subjects on a reasonably sure foundation, and have served to mark out the way to secure any desired degree of stability which may be desired or which may be consistent with other valuable qualities. We are here confronted with one of those situations, so frequently encountered in scientific and technical work, where a choice must be accepted on some middle ground between wide extremes, and where the attempt to secure some desirable quality in high degree may lead to a limitation of desirable qualities in other directions.

#### Desirability of Extreme Stability

So it is with stability and control. If stability is carried to an extreme then mobility and quickness of maneuvering are reduced and control in the sense of ready response is lacking. For military purposes, especially for machines of the fighting type, where mobility is of the highest importance, this would be a serious shortcoming, and hence such machines cannot be given too much stability in the ordinary sense of the term. On the other hand, for heavy machines of the bombing type, where mobility of evolution is not so vitally important, the margin of stability may be greater. Going to a still further extreme, it is perfectly easy to build a safe moderate-speed family carriage sort of machine which will be stable and secure, under almost any conditions likely to develop. Such machines would be scorned by fighting pilots, but when civil aeronautics begins to come into its own after the war and under peace conditions, and there comes a demand for safe machines for civil purposes, including family outings for the week-end from the city to the country or to the seacoast, then we may anticipate a larger recognition of the qualities making for safety and stability, and we shall find machines provided having such characteristics and in practically any desired degree. Here again, however, there will be degrees of choice, because it will be found that

with too high a degree of stability, what may be termed the riding qualities of the plane will be poor, while with low stability the riding qualities may be much smoother.

The general problem is therefore pretty well solved so far as the ground work is concerned. This does not mean, however, that there is nothing further for us to learn in this connection. There are many problems of a detailed nature inviting the student of this fascinating field of study, and the solution of which will serve to round out and broaden our general grasp of the subject. In particular, we need further study on the interaction between elements which insure stability and those which permit mobility and readiness of response to control agencies, to the end that we may control more effectively the combinations which may be desired regarding stability and mobility of evolution.

Again, while the elements of control are well understood, there is room for further study as to the best means of actually developing the control forces required and of applying them to the plane itself. These are partly aerodynamic and partly structural problems, each phase reacting more or less on the other.

#### An Example

One instance of problems of this character will serve to illustrate the type.

Thus, we know that an aeroplane is provided with rudder surfaces of two kinds, one to determine movement in a vertical direction, up or down, and the other to determine horizontal motion, right or left. But these motions, vertical and horizontal, assume that the plane itself is horizontal or sensibly so. However, when a plane is circling on a steep spiral or making a quick turn, it is inclined or "banked," in order to avoid side slipping, until, in extreme cases, the wings are nearly vertical, and frequently much more nearly vertical than horizontal. In such cases, the functions of these control services are reversed. Those which, with normal aspects, serve to produce movement right and left will now serve to determine motion rather in a vertical direction, and those which formerly served for movement up and down will now serve to determine motion to the right or left. For intermediate angles of bank, each set of control surfaces will give control forces in both directions, up or down and right or left.

Now, it is by no means sure, having in view this double and interchanging function between these two sets of surfaces, whether we have as yet realized the ultimate and best arrangement either as regards the surfaces themselves or their control by the pilot.

It seems decidedly probable that we have not and that some arrangement yet remains to be devised which will be more effective in the matter of this double and interchanging function of control, and simpler in its relation to the pilot.

This and other like problems are still awaiting investigation and offer a delightfully promising field for the further study of the aerodynamic engineer.

There still remain two large and important fields, rich in

aeronautic problems. These are armament and instruments. I shall attempt no more than the briefest general reference to these two classes of problems.

Those arising under the head of armament are, of course, strictly military in character, and but little of interest could, in any event, be said in a public address. Such problems relate naturally to the number, type and size of guns to be carried, their mounting and special sights; bombs and devices for carrying, aiming, dropping, etc.; questions of armor and protection of vital parts against gunfire or shrapnel bursts, etc.

Expressed in their most general terms, these problems resolve themselves into an attempt all along the line to meet the requirements imposed by the desired military uses of the plane, and to anticipate or improve upon the devices and designs of the enemy in the same fields.

Regarding instruments, little more specific can be said. This field does, however, bristle with problems of the highest interest to the scientist, and may well challenge his best efforts. It is interesting to note the extent to which the modern aeroplane has become a flying meteorological and physical laboratory. Thus, a recent list of aeroplane instruments shows some 25 or 30 different instruments and devices, not indeed all to be carried on one plane, but all included in the general aeronautic military program, and each serving some specific and important purpose.

With these instruments, as with armament, the problems reduce themselves to an effort to meet the military or the navigational and operative requirements of the situation, and in these days of war in particular, to anticipate or improve upon the similar devices and designs of the enemy.

Much of the work relating to these problems under armament and instruments is already done and well done. There do remain, however, many problems, especially of detail or of improvement, and which must be considered as outstanding; but of these I shall attempt no mention or discussion.

By way of conclusion, reference may, for a moment, be made to a problem of the most vital and far-reaching economic importance, and which will be upon us with the arrival of peace conditions. This is the problem of the best economic utilization of the enormous investment which has been made in aeronautic production, expressed in terms of money and human time and energy, and now represented by factories, machinery and equipment, finished product, trained industrial organizations, human skill and productive capacity.

And so with all our problems; we can only look hopefully forward for the future to give to us such measure of answer as our patience and study may merit.

Of one thing, however, we may be sure, and that is that the day will never come when we have no more problems to solve. But, on the contrary, the number of problems still outstanding, as the years go by, is likely, rather, to increase with our acquaintance with the subject, and we may be sure that before this or any like audience under the auspices of the Aeronautical Society of Great Britain there will never lack material for a discussion of "Outstanding Problems."

and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly),  
July, 1907.

## Sixteen-Cylinder Engines

AS the multiplication of cylinders in automobile engines had been carried to the point marked by the twelve-cylinder or twin six, it was to be foreseen that in aircraft engines, where very much larger powers are called for, this number would be exceeded. One of the first steps beyond the twelve was the so-called W type of engine of 18 cylinders for which a well-known English designer was responsible. It received considerable publicity at the time of its appearance, but little has been heard of it since. The engine was laid out to give uniformly spaced explosions, and, consisting of three sixes on a six-cylinder crankshaft, it was, of course, in absolute balance so far as reciprocating parts are concerned. Probably the most objectionable feature of the engine was its necessarily considerable frontal area and consequent high parasitic resistance. This resistance is less the greater the number of cylinders that are placed in a row and the fewer the number of rows.

A comparatively small parasitic resistance may also be achieved with a 16-cylinder type engine, as the natural angle of V for such an engine is 45 deg., the angle of the Liberty engine. As compared with the 12-cylinder 45 deg. V engine, the 16-cylinder has the advantage of evenly spaced explosions and it also possesses an advantage in respect to parasitic resistance, because with the same cylinder dimensions, arrangement of accessories and general design of the crankcase, the parasitic resistance due to both engines should be alike, while the power output of the 16 would be 33 1/3 per cent greater.

As regards mechanical balance, the 16 is probably not quite as good as the 12. This depends somewhat on the manner of arranging the crankshaft. In all-in-line eights, it has been the custom to use what is virtually two four-cylinder crankshafts joined end to end and set at right angles to each other as regards the throws. We have, therefore, two four-cylinder engines end to end with their cranks rigidly held in synchronism. Each engine has an unbalanced secondary inertia force having twice the frequency of crankshaft rotation. The secondary inertia force of one engine is a function  $\cos 2\theta$ , where  $\theta$  is the angle its crank has passed through from the top dead center position, and the secondary inertia force of the other engine or set of four cylinders is a similar function of  $\cos 2(\theta + 90^\circ) = \cos 2\theta + 180^\circ$ . But the cosine of an angle plus 180 deg. is the negative of the cosine of that angle, hence the two secondary inertia forces will be equal and opposite to each other. However, since one force acts near one end of the engine and one near the other, they do not cancel each other but result in a rocking action in a plane through the crankshaft.

The arrangement of the crankshaft described is undoubtedly used because of the ease of its manufacture. By having alternate throws of the crank at right angles the rocking moment can be almost eliminated.

All the above arguments relate to eight-cylinder engines. Since the inertia forces are reciprocating forces acting in a single plane, those due to one set of cylinders in a V engine cannot be balanced by those due to the other set. Therefore, the balance of a sixteen-cylinder V engine is the same as that of an eight having the same crank design.

## Skilled Acetylene Welding

THE art of acetylene welding will undoubtedly be greatly advanced by the large-scale manufacture of aircraft engines, for most of these engines involve numerous welding operations, some of them of a most difficult nature. Acetylene welding has now been practised for more than a decade, and such welding equipments are found in repair shops all over the country, yet the number of expert operatives is none too great. An ordinary repair job, such as welding up a crack in a cast iron cylinder or an ordinary break in any casting, is easy enough to handle, but when welds have to be made between

very thin sheet metal parts, as is required in welding up the jackets and valve fittings of an airplane cylinder, more than usual skill is required if a neat job is to result. Practice, of course, makes perfect, and with the large amount of work of this class now needed a great many welders will become very proficient at the job.

## The Employment Department

**T**HERE is real cause for wonder at the late germination and slow growth of a good idea in the fact that, measured by the length of time that other modern industrial methods based on the same fundamental principles have been in general use, the employment manager's department is still very new and in fact, is as yet unknown, in many industrial organizations.

Isn't it a bit odd and rather hard to explain that industry as a whole should have so long failed to appreciate the importance of the scientific, not to say the semi-intelligent, selection of its labor elements? Isn't it difficult to understand why we should not long ago have seen, without being shown, the advisability of having our industrial hiring done by one department in each plant with special knowledge, training and equipment for the job instead of leaving it to foremen, superintendents and department heads who, having vacancies to fill, fill them with whatever type, manner or character of applicants happen to apply, if they measure fairly well up to certain not clearly defined standards of their own creation?

Imagine the state of things which would result from having the buying of materials and supplies done in this same decentralized and disorganized manner.

The advantages of the purchasing agent are apparent. The results of his efforts are readily observed, measured and appreciated. With the employment department, however, it is not quite so easy to determine just what benefits are derived, particularly when by benefits we mean financial return. These benefits are real but they do not make themselves so directly manifest. They are hard to calculate on a dollar and cents basis except after a comparatively long period of time.

Now that the United States Government has taken a strong hold of the labor situation and pretty well controls the unskilled supply, the employment manager has become an industrial agent in whose doings the Federal authorities take a direct and active interest. Labor is so scarce, it must be used economically. Every man must do what he can do best. The worker must be assigned to the kind of work for which he is best fitted through past experience, temperament and natural inclination. It is no time, from either the point of view of the individual manufacturer or the nation as a whole to permit waste effort and inefficiency resulting from unscientifically combined men and jobs.

The Government is so thoroughly alive to the importance of the efficient distribution of labor that it is conducting courses of instruction for the training of employment managers.

## Americanization from the Practical Point of View

**T**HE manager of an electrical equipment manufacturing plant chiefly engaged now on Government work, recently complained that the greatest obstacle in the way of obtaining desired and necessary production in his organization is not so much a lack of workers or capacity of equipment as it is indifference on the part of the operatives. He described this indifference as a lack of patriotism, as a failure to appreciate the need for whole-hearted and continuous effort at this particular time. He disclosed the fact that most of the operatives who manifested a spirit of disinterestedness were foreign-born, but not enemy aliens. Patriotism does not, of course, move such as these. What this plant needs, and so we told its manager, is to be Americanized.

Others, many of them, have met this same condition. In many plants, forced to run with a large proportion of a lower grade of foreign-born and often non-English speaking workers, there is noted a very marked check on production, beyond a certain comparatively low limit which arises from indifference on the part of these workers to the benefits of piece-work rates and other inducements which seemingly should affect their selfish natures, but apparently do not, beyond a given point. There is evidence aplenty that Americanization in such cases will work wonders, that it will do what bonuses, premiums and other usually effective production stimulants fail to accomplish.

Americanization, that is industrial Americanization, is not, as the condition described will testify, a philanthropic movement. It is purely commercial, purely a production building undertaking. And the fortunate part is that it benefits both employer and employed, one as much as the other, if indeed it does not benefit the latter more. This, however, from the point of view of the employer, is merely incidental. His interest in the movement lies in its practical results as they may be observed in his business records.

Looking at Americanization in this coldly practical way, it can be said that it has been found to be a good, and in many cases a necessary, investment. Workers, to be good workers, to be the kind of workers that make for maximum production, must have the American point of view. They must have American ideals and ambitions. They must first of all speak and read our language. They must like our country well enough to become citizens of it. They must feel that their home is here and that this is the land in which they will experience the realization of their highest hopes.

A number of our big business organizations have come to realize the importance of this great truth. In our own industries there are several excellent examples of what can be done along this line. There should be more and those who apply the principles involved should not be only the larger concerns. The smallest one in any industry is not too small to benefit by the thorough Americanization of its employees.

## Motor Trucks Under Quartermaster

### Colonel Glover Placed in Charge of Purchasing, Production and Procurement of All Vehicles by Order of General Goethals

WASHINGTON, Sept. 11—Following closely upon the creation of the Motor Transport Corps, new orders inaugurated by Major General George W. Goethals, assistant chief of staff, take the purchase, production and procurement of motorized army vehicles from the new corps and again place these duties under the Quartermaster Department in charge of Colonel Fred Glover who was transferred from supervision of this work less than a month ago.

Colonel Edwin S. George, who worked with Colonel Glover and was also transferred, is again in charge of production.

Colonels C. B. Drake, James F. Furlow and C. Seamon remain in charge of the Motor Transport Corps which now controls the engineering, operation and maintenance of motorized army vehicles.

#### Rearrange Whole Plans

The Motor Transport Corps will instruct Colonel Glover of the army needs and it will be his responsibility to meet these requirements.

Complete rearrangement of practically the entire army plan of operation preceded these moves. At the direction of General Goethals who is also Director of Purchase, Storage and Traffic, orders were issued recently and speedily making him the direct chief of all purchases and ordering General W. Wood, Quartermaster General, to report directly to General Goethals. Following this, additional orders were as speedily promulgated taking the control of purchase, production and procurement from the Motor Transport Corps and again placing it under Colonel Glover.

These changes come most abruptly regarding the program of army truck activities. There has been considerable jockeying for control of the army truck activities. First there was the Motor Transport Section of the Quartermaster Department in charge of trucks under Brig. General C. B. Baker who favored the standardized trucks designed especially for the army. Last spring, after continuous attacks upon these war trucks, the control of trucks was taken from General Chauncey B. Baker. A Motor Transport Service was organized under Colonel F. Glover with the aid of General Goethals. Tests were held and some of the standardized war trucks were discarded in favor of standard makes of trucks. After about 10 weeks of control following Secretary Baker's return

from Europe, the Motor Transport Service was abolished, Colonel Glover was transferred, and the Motor Transport Corps was created with the same men in charge who had been under General C. B. Baker. This was within the last 30 days. Now comes the new abrupt change, following Secretary Baker's return to Europe, with Colonel Glover again in charge.

The opinion was expressed in Washington that the creation of the Motor Transport Corps with the regime favoring standardized trucks in charge meant that the truck policy of the Army was permanently settled. Officials told of past lobbying and politics and claimed that the "election was over." Apparently they were incorrect. A recount, it seems has been taken.

At the same time that General Goethals was hurrying these orders through, it appears that those interested in maintaining the Motor Transport Corps were rushing orders through to gain more substantial control for that Corps. The orders from General Goethals were somewhat speedier and more powerful.

In consequence of these rapid changes civilians and officers, four weeks ago under the Motor Transport Service, suddenly found themselves under the Motor Transport Corps and now as abruptly find themselves in the Quartermaster Department as all those connected with purchase, production and procurement, including the branch offices in New York, Cleveland, Detroit and Chicago some under Colonel Glover. It is expected that there will be some transfers, resignations and appointments.

#### Changes Cause Confusion

As a result of these many changes considerable delay and confusion exists. While the changes have been in process army truck plans have been neglected. In addition there is the confusion of the reorganization. Up to late last week the Motor Transport Corps had no knowledge of the new change and proceeded to build up an organization calling upon many important individuals who in turn proceeded to give up their present connections to come to Washington. Some of these men have arrived and they do not know now what positions they hold or what to expect.

Following is a circular by General Goethals explaining the organization of and assignment of duties as regards pur-

chase in the Army, and also the supervision of the Quartermaster Department.

Subject: Organization of the Division of Purchase and Traffic, General Staff

1. Organization of and assignment of duties in and under the direction of the Division of Purchase, Storage and Traffic, General Staff, shall be as follows:

(a) Office of the Director of Purchase, Storage and Traffic, General Staff.—Duties: Responsibility for and authority over—

(1) Supply of the army, including analysis and computation of requirements, purchase, production, inspection, acceptance, transportation, storage, issue within the United States and embarkation.

(2) Relations with all other agencies, governmental and otherwise, in regard to army supply, including representation of the War Department on the War Industries Board and business with representatives of the allied governments.

(b) Facilities Department.—Duties: Responsibility for and authority over procurement of real estate.

(c) Accounts Department.—Duties: Responsibility for and authority over disbursements, fiscal accounting, preparation of estimates, and reports of accounts.

(d) Traffic Department.—Duties: Responsibility for and authority over inland transportation.

(e) Embarkation Department.—Duties: Responsibility for and authority over embarkation and ocean transportation.

2. (a) The Quartermaster General of the Army shall report to the Director of Purchase, Storage and Traffic.

(b) The Quartermaster's Department, in addition to its other duties, shall have responsibility for and authority over storage, distribution, and issue within the United States of all supplies for the army.

(c) The chiefs of all other bureau corps, and departments of the army shall report to the Director of Purchase, Storage and Traffic on all matters enumerated in section 1 (a) hereof.

3. The present supply organization of the army shall continue as heretofore until changed by orders issued by this office from time to time.

By authority of the Secretary of War.  
GEO. W. GOETHELS,  
Major General, Assistant Chief of Staff, Director of Purchase, Storage and Traffic.

#### Motor Transport Corps to Consist of 154,774 Men

WASHINGTON, D. C., Sept. 12—An additional statement regarding the Motor Transport Corps was issued here to-day and says that this corps will eventually number 154,774 men. The army motor trucks with this corps will number 40,803. There will be 24,250 motorcycles, 7905 passenger cars, and 6598 ambulances with a total of 100,000 riders and drivers. There will be 4298 officers and 30,090 non-commissioned officers. The executive organization will comprise 3122 men and 679 officers and the total repair personnel in the 273 service parks which will be constructed for the upkeep of the vehicles, will comprise 34,319 men, mostly trained mechanics.

Each additional American army will require a similar motor transport personnel and it is expected that by the time the United States has 4,000,000 troops in France, 500,000 of them will be engaged in motor transport work. The Motor

# Automotive Industries □

## To Maintain Average Truck Output

May Produce During Last Half of Year One-Third Made During Last 18 Months

NEW YORK, Sept. 10—Manufacturers of motor trucks are to be permitted to maintain production during the last half of 1918 at the average reached during the past 18 months. They are to receive priority ratings in class B4 for such materials as may be necessary to produce during the period July 31 to Jan. 1, one-third of the number of vehicles produced for civilian use during the whole of 1917 and the first half of 1918.

The certification of Priorities Certificates which will enable manufacturers to obtain raw materials and parts already has been commenced by the Automotive Products Section of the War Industries Board, and these are now being cleared by the Priorities Division. Such certificates, it is pointed out by the National Motor Truck Committee of the N. A. C. C., cover only vehicles intended for civilian uses, which take a B4 rating under the ruling of the War Industries Board, and not trucks built for war purposes, which may take a higher rating.

It is believed that manufacturers of road tractors, trailers, truck attachment units of the truck-former type and body builders who build for the trade and do not dispose of their entire outputs to manufacturer will come within the same classification as the truck manufacturer. Where they have not already done so, they will be required to supply the Automotive Products Section with sworn statements of their production during 1916, 1917 and the first half of 1918.

In its statement, the National Motor Truck Committee says: "It is felt that the board will not look with favor on any increased production beyond the average of the last 18 months. Indeed it will be disappointed if sales are not reduced. In view of trucks being sold only to essential industries, it is expected that substantial savings will be made from past production. So you should constantly bear in mind that the number you may be permitted to make by the terms of the Industry Certificate issued you does not justify you in making such number unless such number is necessary to supply your demand from essential industries."

In those cases where production of individual companies shows a reduction during the first half of 1918 as compared with the previous year, due to

heavy production of military vehicles, the allotment has been reduced to a basis of the production for the first six months of 1918, on the expectation that continuing or expected additional war orders will counterbalance the reduction; and in cases where companies were not in real production during the last of 1917 the allotment has been based on the average of production during the time they were in production.

When approved by the Priorities Division, certificates will be mailed or delivered to the manufacturer. These will authorize him to purchase the necessary materials to complete the specified number of trucks and will contain a form of affidavit which must be attached to each order for material. This affidavit is the only receipt needed by the supplier to release the materials.

The new arrangement supersedes the older one requiring individual priority certificates for each order. Priority certificates that have already been filed with the board will not, therefore, be acted upon.

### Urge Abandonment of Shows

WASHINGTON, Sept. 12—Following the cancellation of the National Automobile Shows by the National Automobile Chamber of Commerce the Chamber and the War Industries Board are urging promoters of local shows for automobiles trucks or accessories to abandon all plans for such during the coming winter to save fuel, labor and transportation.

In a statement issued here to-day it is said that the Chamber cancelled the 1919 shows at the request of Bernard M. Baruch and George M. Peek of the War Industries Board. Following a meeting here between Baruch, Peek, Alexander Legge, Judge E. B. Parker and all of the War Industries Board and Hugh Chalmers and Alfred Reeves of the Chamber, a letter was sent to the Board to the effect that the Chamber concurred unanimously in the opinion of the Board and adopted the following resolution:

"Resolved that the promotion of National Automobile Shows during the winter of 1918-1919 with consequent use of transportation, fuel and labor would in the opinion of this body be inconsistent with patriotic obligations of the industry and that therefore national shows be suspended until further action of the association.

Resolved that the reasons expressed in the foregoing resolution promoters of local and other shows be respectfully requested not to hold automobile truck or accessories exhibitions during winter 1918-1919."

## Preference List of 74 Industries

Aircraft Leads Activities Entitled to Preferential Treatment—To Name Plants

WASHINGTON, Sept. 8—Seventy-four industries are named in a new preference list, just compiled and issued by the War Industries Board, as the primary industries of the nation, entitled to preferential treatment because of war or national interest demands. The industries, named, together with a list being compiled of 6500 individual plants engaged in whole or part on war work, will receive preferential treatment through priorities on all matters of:

Fuel	Materials
Labor	Transportation
Capital	Facilities

The list will also be used by the War Department as the guide for allowing industrial exemptions from the draft.

The numerous factories listed individually are so handled because the industries to which they belong were not entitled to preferential treatment as a whole. "In numerous instances," says the War Board, "individual plants have been found entitled to high preference while the industry to which they belong is not."

Motor trucks for example are not specified in the list of industries and those truck plants entitled to preference treatment will be listed individually, as will passenger car and motorcycle manufacturers engaged in work entitled to preference in priorities.

The industries are arranged in four groups, group No. 1 being the most important. While those in group No. 2 are chiefly more important than group No. 3 and No. 3 is more important than No. 4, there are many instances where an industry though no more important than another is given a higher class rating because its production is not equal to the demand and special preference is extended in order to supply the materials, transportation or labor as the case may be, so that the production of that industry may be speeded.

The industries named that are of particular importance because of their connection with automotive activities are as follows. The group classification is also shown:

Aircraft .....	I
Ammunition .....	I
Small arms .....	I
Blast furnaces (producing pig iron) .....	I
Brass and copper (plants engaged prin-

## Restrictions in U. S. Affect Canada

### No Maker of Complete Cars in Dominion—Dependent on United States for Parts

MONTREAL, Sept. 10—Some people might imagine that the Canadian end of the industry is not much affected by decisions of the U. S. War Industries Board, but a little thought will show the fallacy of this. Canada does not possess to-day an automobile manufacturing plant that is complete in itself.

Most of the parts of the cars that are made in Canada are, it is well known, manufactured in the United States and are assembled in Canada, only a small proportion of the actual production being done in this country. This is unfortunate, but it is nevertheless true.

### Shortage of Steel

Consequently any restrictions that are put upon the manufacture of parts in the United States affect the supply to Canada, and it is sure that the industry in the States is not going to supply Canada when it cannot supply its own needs. This particularly applies to steel, while apart from this the Canadian Government regulates every pound of steel that comes into the country, and it is so much needed for munitions work that there is not even any available for the manufacture of rails for the railroads.

There will be practically no new models for 1919, for not only are the designers engaged in more important work but with the increased restrictions on manufacture there is no object in making expensive experiments now in order to secure an improvement which with the rapid strides that engineering science is making under the stress of war may have to be discarded for something better when the war is won.

### Trucks and Tractors Only Hope

Dealers who are hard hit by present conditions are keeping a smiling countenance and doing the best they can with what is at their disposal, hoping always for the best.

The only automobile construction work that is likely to be done anywhere in the Dominion next year will be in the building of trucks and of tractors and other automobile machinery which will aid in the production and transportation of necessities. There are some agencies in Montreal that have already been notified that the passenger car portion of their firms has been entirely suspended and that the trucks are all that will be turned out in limited quantities for the general market.

The agents will presumably turn their attention to the development of the truck industry, and in this way the restrictions that are being placed on the whole industry will be somewhat of a blessing in disguise. So big has been the demand for passenger cars in the past that agents who have handled both truck and pas-

senger cars have not devoted so much attention as they might have done to the transportation vehicle.

### Canadian Ford Stops Dividends

WINDSOR, ONT., Sept. 6—The Ford Motor Co. of Canada has only paid 5 per cent in dividends to shareholders in the past few years, and announces that further dividends will not be paid for some time to come. This is due principally to the fact that all the reserves were used in purchasing materials with which to keep the plant in operation, not merely for the next season but for several years.

During 1918 selling prices have been increased 20 per cent, while the cost of production has increased 24 per cent, compared with a 7 per cent decrease in selling prices and a 14% per cent increase in cost for 1917.

A comparative balance sheet of the Canadian Ford company for the past 4 years follows:

Accounts receivable and stock on hand.....	1918	\$8,498,280	1917	5,167,039
	1916	4,916,197	1915	2,678,651
Cash on hand.....	1918	177,252	1917	2,066,455
	1916	486,655	1915	2,809,977
Plant extensions.....	1918	1,072,495	1917	400,000
	1916	1,067,934	1915	1,359,557
Tax payments.....	1918	84,309	1917	596,239
	1916	286,486	1915	697,323
Percentage increase in stocks and plant.....	1918	42%	1917	28%
	1916	46%	1915	31%
Percentage of increase in stocks and plant bears the following proportion to profits	1918	211%	1917	95%
	1916	137%	1915	47%
Selling Price Cost Prod.				
Percentage of selling prices and cost of production.....	1918—Inc.	20%	Inc.	24%
	1917—Dec.	7%	Inc.	14%
	1916—Dec.	10%	Inc.	9%
	1915—Dec.	9%	Inc.	64%
Wages percentage of total expenditure on production.....	1918—16%		1917—16%	
	1916—22%		1915—21%	

### Tire Filler Makers Convene

CHICAGO, Sept. 9—Twelve manufacturers of tire filling products have called an "Automobile Tire Economy Conference" to be held in the Congress Hotel, Sept. 15 to 18. The object of the gathering is to form a national association of standard tire filler manufacturers and to submit to government bureaus a wartime program for salvage of tires. Frank D. Mayer is temporary secretary. The tire filler manufacturers interested are: The Essenkay Products Co., Chicago; Peerless Tire Filler Co., Chicago; Dahl Punctureless Tire Co., Minneapolis; Pan-American Rubber Co., Milwaukee; National Rubber Filler Co., Midlothian, Tex.; Panama Rubber & Equipment Co., St. Louis; Wolverine Tire Cushion & Accessory Co., Detroit; Rubberair, Inc., New York; Bettern-Air Co., Philadelphia; National Synthetic Tire & Rubber Co., New York; Universal Tire Filler Co., Portland, Ore.; National Tire Cushion Co., Kansas City.

## First Jobber Exhibit Abandoned

### N. A. A. J. Ascribes Same Reason as N. A. C. C.—Municipal Pier Show to Be Held

CHICAGO, Sept. 9—The National Association of Automobile Accessory Jobbers has decided not to hold its show, which was scheduled for the week of Oct. 28 to Nov. 2, at Medinah Temple. The reasons for calling off the exhibition are the same as those given by the National Automobile Chamber of Commerce for calling off the national shows. It is probable that the annual convention of the N. A. A. J., which is to be held at the same time, will be carried through with the show feature eliminated. This decision was announced in a bulletin sent to all members Saturday by Commissioner William Webster.

Abandonment of the national motor car shows at New York and Chicago and the jobbers' show leaves the exhibition at the Municipal Pier, known as the National Exposition of Automotive Accessories, as practically the last event of the kind on the program. This exhibit, which opens Saturday, Sept. 14, and runs until the following Saturday, has a good list of exhibitors, particularly of accessories. In addition, there are a number of tractor, truck, truck former, and parts manufacturers who are among the list of exhibitors. Passenger car exhibits will be only incidental.

It is probable that the Pier show will benefit somewhat by the discontinuance of plans for the jobbers' exposition, because there undoubtedly are several jobbers who will take space in the Pier show now that the one at the Temple is not to be staged. Reservations of space are being held open until Wednesday on this account.

Arrangements have been made in connection with the exhibition at the Municipal Pier for a series of conventions to be held there, among which are agricultural organizations, hardware trade and others.

Plans are all in shape for the opening Saturday and the decorations are about completed and the novelty of the show at the Pier may be depended on to attract a number of people who otherwise would not attend. Transportation facilities are exceptionally good, parking space for hundreds of cars being provided and both the surface lines and bus lines provide other transportation.

### England Has Repair Problem

LONDON, ENGLAND, Aug. 20—A recent report shows that there are now in England several thousand motor vehicles awaiting repair and that this number is practically three times what it was a year ago. In France it is reported there is almost an equal number of vehicles in this condition. It is expected that it will take two or three years to put all of these vehicles in good order and dispose of them following the com-

pletion of the war. On the completion of the war there will be a great number of trucks, automobiles, motorcycles and spare parts, as well as machinery that will be brought from France to England, which will represent the value of many millions of pounds. Spare parts for motor vehicles now in government stores are valued at \$25,000,000.

#### Wrench Makers Conserve

NEW YORK, Sept. 6—Manufacturers of drop forged wrenches have adopted a war conservation program for the period of the war. They will discontinue immediately the manufacture of regular finished wrenches in addition to a long list of other wrenches which are considered unnecessary. Semi-finished wrenches may later be eliminated also and their place taken by what is styled a war finish wrench which will be equally as good as the others though slightly different in appearance.

Wrenches will no longer be packed in separate envelopes and all-wooden boxes, and sample and display boards for advertising them are eliminated. The lines retained as necessary are: Engineers' wrenches, check nut wrenches, light cap screw wrenches, hexagon box wrenches, square box wrenches, flat handle "S" wrenches, set-screw wrenches, tool post wrenches, single-head socket wrenches, spanner wrenches, construction wrenches, structural wrenches, round handle track wrenches, car wrenches and light service wrenches, all of which have useful functions to such an extent as to make their elimination doubtful from the viewpoint of conservation.

Those discontinued are all so-called heavy cap screw wrenches, including all millings from those blanks; 22½-deg. angle or textile wrenches, including all millings from that line of blanks; concave "S" wrenches, machine wrenches, long flat handle wrenches, double-head socket wrenches and all miscellaneous wrenches not mentioned in the above paragraph.

#### Fordson Distribution in Canada

DETROIT, Sept. 9—Arrangements have been made whereby the Fordson tractor will be handled by the Ford Motor Co. of Canada, Ltd., through its branches and dealer organizations from coast to coast. Shipments have been made to Ford dealers throughout this section. The tractor will sell to the consumer at \$950 f.o.b. Dearborn, plus the freight to destination. The Canadian government had 1073 tractors delivered to the various provinces in accordance with arrangements made with Henry Ford & Son as a means of assistance in the production campaign carried out by the Canada food board.

#### Wood & Spencer Expands

CLEVELAND, Sept. 6—The Wood & Spencer Co., engaged in the manufacture of machine parts for airplanes and other war munitions, has leased two parcels of land directly in the rear of the factory. The property, which is 78 by 158, was acquired for expansion after the war.

## Export Lines Drawn Tighter

### New Regulations Restrict Licenses to American Firms or Allies of America

WASHINGTON, Sept. 10—New export regulations, effective after Sept. 20, 1918, regarding requests for export licenses, have been made public to-day by the War Trade Board as follows:

Hereafter licenses may be granted by the War Trade Board only upon application of the consignor and only to—

(1) Corporations organized under the laws of the United States, or of any State, Territory, or Possession of the United States or of the District of Columbia, or

(2) Residents of any State, Territory, or Possession of the United States or of the District of Columbia, or

(3) Foreign partnerships with a member who is a resident of any State, Territory, or Possession of the United States, or of the District of Columbia, or

(4) Foreign corporations actually maintaining in any State, Territory, or Possession of the United States or in the District of Columbia an established branch or agency for the regular transaction of its business, or

(5) Any foreign government acting through any member of its embassy or legation accredited to the United States, or

(6) The Traffic Executive of Great Britain, France, Italy, and the consul for Belgium, or

(7) Any official, firm, or corporation appointed by any department or agency of the United States Government to act in its behalf.

Applications for export licenses and supplemental information sheets and any other supplementary documents or letters relating thereto will only be considered by the War Trade Board when filed by such corporations, firms or individuals and only when signed in ink by—

(a) An official duly authorized to act on behalf of a corporation if application for an export license is made by a corporation.

(b) A member of a firm, if application for an export license is made by a firm.

(c) An individual himself, if application for an export license is made by an individual.

(d) A regular employee of a corporation, firm or individual making an application for export license if such employee has been duly authorized in writing to so sign on behalf of such corporation, firm or individual and if such authorization has been filed with the War Trade Board.

(e) An attorney in fact of a corporation, firm or individual making application for an export license, if such attorney has been properly authorized so to act by virtue of a power of attorney duly executed and filed with the War Trade Board.

(f) A person duly authorized to act in their behalf if application for an export license is made by a foreign government, the Traffic Executive, the consul of Belgium, or an agency of the United States Government.

#### Canada Has 237,172 Cars

MONTREAL, CANADA, Sept. 10—The Montreal Automobile Association has compiled the following statistics of automobile licenses issued for 1919 to date in the various provinces:

Prince Edward Island.....	564
Nova Scotia.....	7,290
New Brunswick.....	1,500
Quebec.....	23,337
Ontario.....	97,500
Manitoba.....	22,214
Saskatchewan.....	44,267
Alberta.....	27,000
British Columbia.....	13,500

Total.....237,172

Ontario also has registered 7000 trucks in addition to passenger cars.

#### Australia Needs Battery Men

SYDNEY, AUSTRALIA, Sept. 2—Facilities for looking after storage batteries in some of the more remote sections of Australia are so chaotic that they practically do not exist. In many of these places there is no possibility of getting a battery charged or even buying distilled water for it. The automobile owners in these territories know how to drive cars and that is about all.

Owners of cars requiring their batteries recharged in many cases send them 120 miles where they are charged at the silver mines, where charging is done as a favor by the mine manager or engineer. The mine manager frequently makes distilled water and is dominated by the thought that so long as the water is thoroughly boiled and allowed to cool off, it can be classed as distilled water.

This whole situation points to the need of American manufacturers giving some aid to Australian automobile dealers who ask that certain of their cars be fitted for such a country as this. This calls for magneto equipment and elimination of the electric starting and lighting equipment. Many large owners of sheep farms, or station owners, as they are called, have no facilities whatever for making electrical repairs, and the difficulty of handling a car with complete electrical equipment becomes very apparent. This does not mean that the electrical systems are not good, but while they are ideal for the most populous sections of Australia, they are not fit for the more remote sections which are developing into large car-buying areas.

#### Detroit to Care for Wounded Soldiers

DETROIT, Sept. 10—Plans are being made by the employment department of the Detroit Board of Commerce to take care of incapacitated soldiers and sailors returned from service, and the co-operation of industrial plants has been requested in the work.

## July Exports Are 1% Below June

Tractor Engines and Airplane Parts Show Substantial Gains for Month and Year 1918

1918					
Cars	Value	Trucks	Value	Parts	
July..3,442	\$3,624,870	601	\$1,527,519	\$2,771,193	
June..3,098	2,808,463	829	2,001,488	3,195,353	
1917					
July..5,089	\$3,627,217	1,388	\$3,562,755	2,139,938	

WASHINGTON, Sept. 10—Exports of passenger cars, trucks and parts (not including engines and tires) during July amounted to \$7,923,582, as against a total of \$8,005,304 for the previous month, a loss of but little over 1 per cent. When compared with the total for July, 1917, the falling off for the month is approximately 15 per cent.

A greater number of passenger cars were shipped during July than was the case in June, but both months fall far behind the total for July, 1917.

Exports of commercial cars show a steady decrease from those of 1917, but the value of parts, although lower for the month, show a gain on the year's figures. A significant increase is shown in both the number and value of tractor engines exported. This classification includes engines used for military tractors of creeper type. It should be noted that airplanes exported for military use are not included in the figures given.

Australia proved to be our best cus-

tomor for passenger cars in July, the United Kingdom leads as a truck buyer and the substantial car exports to Latin-American countries indicates improved shipping conditions. Airplane parts exported during July were valued at \$1,913,127 as against \$261,565 for the same month of 1917.

### \$5 a Day Granted by Canadian Ford

FORD CITY, ONT., Sept. 9—Approximately 2500 employees of the Ford Motor Co. of Canada, of which 1900 are employed at the Ford City plant, will benefit by the new \$5-a-day wage scale for 8 hr. which took effect to-day. This will affect every employee of the Canadian plants who has been in the service of the company for 3 months or more. The former minimum wage was 50 cents an hour. Canadian plants are located at Montreal, Toronto, London, Winnipeg, Saskatoon, Calgary, Vancouver and St. Johns, N. B. War conditions and lack of material have compelled the company to cut its staff considerably, but it is using all the men possible at the present time.

### August Acme's Record Month

CADILLAC, MICH., Sept. 9—The Acme Motor Truck Co. had the best month in its history during August. More trucks were sold and more delivered than at any other time since the Acme was placed on the market, and the outlook for future business is reported by officials to be most satisfactory. More agencies are being established and the company's advertising campaign is proving very effective.

## New York's Exports Drop Slightly

July Figures Show a Gain in Passenger Cars and Parts —Trucks Show 46% Loss

NEW YORK, Sept. 9—Although during July both cars and parts exported showed a gain when compared with the figures for June, the falling off in truck exports was sufficiently large to bring the grand total below that of the latter month.

The comparative values are as follows:

	Cars	Trucks	Parts
June .....	\$1,495,346	\$1,370,955	\$767,276
July .....	1,667,464	741,132	1,068,384

The grand total for July is \$3,476,980 as against \$3,633,577 for the previous month. July's exports were a trifle better than those of May, which showed a total of \$3,339,558.

Chile was our best customer for passenger cars in June, taking delivery of 287 during that month. Australia heads the list for July with 293 passenger cars.

Evidence of better shipping facilities is given by Spain taking 87 cars as against 3 during June, and our trade with Latin America is well maintained. Japanese China and Ireland appear in the July table and France's purchases represent over half our month's truck exports in number and two-thirds of the total value.

## Exports of Automotive Equipment for July and Six Previous Months

	Month of July				Seven Months Ending July, 1918

## Rubber Imports Decline

August Receipts 5,671 Tons  
Behind Last Year—Six  
Months Totals Ahead

NEW YORK, Sept. 10—Imports of crude rubber slumped considerably during the month of August as compared with July, the net decrease being 5671 tons. During July, 16,092 tons came in as compared with 10,421 tons in August. The total for the year to date is still ahead of the total for 1917 up to the same time, though the ratio of increase has dropped slightly as compared with the total to the end of July. There has been a gain of 3321 tons imported as compared with a similar gain of 10,189 tons reported at the end of July for the seven-month period.

During the first eight months the total quantity imported was 125,891 tons. This compares with a total of 122,661 tons that came in during the same period in 1917. Following are the statistics as compiled by the Rubber Association of America:

Month	1917 Tons	1918 Tons
January .....	12,788	16,084
February .....	10,182	13,108
March .....	18,624	17,161
April .....	13,000	12,703
May .....	18,411	16,288
June .....	15,096	24,124
July .....	17,290	16,092
August .....	17,290	10,421
Total .....	122,661	125,981

### Ryan and Baker in France

WASHINGTON, Sept. 9—Secretary of War Newton D. Baker, accompanied by John D. Ryan, Second Assistant Secretary of War in charge of military aircraft, has arrived in France. It is expected that a complete investigation of aerial activities and aircraft needs will be made. Secretary Baker, accompanied also by the Chief of Embarkation and the Surgeon General, intimated before leaving that the purpose of his journey would be made clear by the interests of the men who crossed the Atlantic with him. Coming closely after the Senate Military Affairs Committee airplane re-

port, the sudden decision of the Secretary of War to visit Europe is taken by many here to mean an intensive study of air needs and possibilities at the front.

### Gear Makers to Meet Sept. 20-21

SYRACUSE, Sept. 9—The semi-annual meeting of the American Gear Manufacturers Association is to be held at the Onondaga Hotel, Sept. 20 to 21. Following is that portion of the program which has been completed: "Priority," Charles A. Otis of the Priority Committee; "What Is the Possibility of Women Becoming a Permanent Factor in the Gear Industry," W. H. Diefendorf; "Trade Acceptances," C. E. Crofoot; "The Outlook of the Steel Supply," C. E. Stuart, secretary and treasurer of the Central Steel Co., Massillon, O.

### Canada Conserves Gasoline

MONTREAL, Sept. 10—Canada has fallen in line with the policy which went into effect across the line a few days ago of conserving gasoline by refusing to sell to owners on Sundays. The Imperial Oil Co. has led the move, and all Imperial service stations in Canada will be closed on Sunday, this ruling to be effective for the duration of the war. An announcement has been received from Ottawa which will make the measure Dominion wide.

### Gasoline and Oil Exports Run Into Big Figures

WASHINGTON, Sept. 7—Figures issued to-day by the Bureau of Foreign and Domestic Commerce deal with the exports of various oils and gasoline for the month of July and also for the seven months ending with July of 1918 and 1917.

On a seven months' basis substantial gains are shown in crude mineral oil, gasoline and naphtha and residuum and fuel oil. Both illuminating and lubricating oil show a decrease. Taking the seven months of 1917 against a similar period in 1918 the latter year shows a total gain of \$60,926,383 in value of exports of this class and 120,697,443 gal. in quantity. The remarkable gain in fuel oil may be accounted for by the increasing needs of oil-burning naval and merchant vessels.

## Navy Airplane Base at Galveston

Mammoth Plant to Cost \$3,-  
000,000 and House 1200 Men  
—Nine Hangars Planned

GALVESTON, Sept. 10—As a result of a revision of the plans of the Navy Department for the construction of a naval air station here the total cost of the improvements will be more than three million dollars, or nearly double the original estimate. The proposed plant will consist of nine large hangars, repairshops, officers' and student aviators' quarters, barracks and medical quarters, for the accommodation of approximately 1200 men. Of this number about 1000 will be ground men and mechanics, 100 officers and 150 student aviators.

Each of the nine hangars will be 104 x 105, and will accommodate four machines. The first plans considered by the Navy Department called for six hangars and twenty-four sea-planes.

The site is 60 acres, between the railroad tracks leading out of the city and the bay. Three hundred and fifty thousand yards of dredging will be required for the work. Around the front and two sides of the 5-ft. elevation will be built a wooden bulkhead and an earthen levee around the back or south end. From 4800 to 4900 lineal feet of bulkheading, or filling material, will be required for filling in the dredged-in portion of the property. The basin will be dredged to a depth of 5 ft. the entire length of the building for a take-off, which will be 200 ft. in length. Construction will begin immediately.

### More Money for Continental Parts

KNIGHTSTOWN, IND., Sept. 6—Continental Auto Parts Co. has increased its capital stock from \$10,000 to \$50,000, and is now making extensive additions to its plant and installing additional machinery and equipment in order to take care of its Government contracts. The company manufactures a line of shop and factory equipment.

### Comparative Exports of Gasoline and Oil for 1917-1918

	JULY				SEVEN MONTHS ENDING JULY			
	1918		1917		1918		1917

## Résumé of Allied Airplane Bombing

### British Ministry Reports Remarkably High Average of Enemy Machines Downed Each Week—Ineffectual German Retaliatory Measures

WASHINGTON, Sept. 10—Little detailed information regarding the amount of air bombing now being carried on by the Allies has heretofore penetrated to this country, though intensive air bombing is constantly increasing and few German cities within a radius of 250 miles of the airplane bases have escaped. Consequently the following résumé of operations during a recent week by the British Royal Air Forces is particularly interesting and illustrative of the enemy's air losses and the numerous raids which are being carried on daily. Following is the complete résumé issued by the British Air Ministry:

Those who follow closely the news of the war in the air have been impressed by two things:

The first is the consistent and remarkably high average of enemy machines destroyed week by week. The second is the singularly spasmodic and obviously nervous way in which Germany seeks to carry the three-fold British aerial offensive which is being sustained against her.

#### Enemy's Heavy Air Losses

Taking the figures for the past week for example, 70 enemy machines have been destroyed and 11 driven down out of control by British airmen on the Western front alone. During the same period 27 British machines were reported missing; thus, for every British airplane which failed to return to its base, more than two German machines are known to have been smashed.

That these figures are by no means exceptional is shown by the fact that during the last four weeks 324 enemy machines have been accounted for under similar circumstances, while only 116 British have been reported missing.

The same broad results are observed upon the Italian, Balkan and Palestine fronts, where 18 enemy machines have been destroyed or driven down out of control. During the last week 12 British machines have been reported missing. Taking the whole of the European Mediterranean battlefields together, the Royal Air Force has accounted for in the neighborhood of 120 enemy aircraft against a net loss of 29 British machines.

#### Britain's Triple Air Offensive

It is, however, upon the Western front that this remarkable disparity is most significant, for it is here that Germany is concentrating the major portion of her strength. It is here also that she is faced with the three-fold problem, not only of defending her long battle front, but also of warding off the insistent and formidable British attacks upon her right and left flanks—Belgian naval

bases—and the industrial centers on the Rhine.

#### A Week of British Air Raids

Some idea of the scale of Britain's effort in this quarter can be gained from the following list of successful bombing raids undertaken by the Royal Air Force on the Western front during the past week:

Raids Into German Territory	No. of Raids
Offenburg .....	3
Stuttgart .....	2
Saarbrücken .....	2
Barden .....	2
Coblentz .....	2
Hagenau .....	1
Nahr .....	1
Rastatt .....	1
Söllingen .....	1
Pforzheim .....	1
Dürren .....	1
Traves .....	1

Raids Into Belgium	No. of Raids
Ostend Docks .....	4
Bruges Docks .....	3
Zeebrugge Docks .....	2
Westende .....	2
Nieuport-Ostend Canal .....	1
Nieuport-Bruges Canal .....	1
Middlekerke .....	1
Aerodromes and dumps .....	4

Innumerable raids have been made on all fatal enemy positions, including Seclin, Lille, Menin, Cambrai, Valenciennes, Cortrai, Armentieres, Douai, Bapaume, Chaumes, Peronne, etc.

#### Intense Local Air Fighting

The highly damaging results to the enemy of these incessant raids is strikingly shown, not only by the photographic records by our pilots, but by the spasmodic attempts of the enemy to frustrate them.

By withdrawing urgently needed machines from other fatal points, he has occasionally been able to secure a local numerical superiority, as was the case last week at Mannheim, where, in the course of an early morning raid, we lost seven machines after "bitter fighting." This fact, however, did not prevent the Royal Air Force from renewing their attacks on Mannheim the evening of the very same day when, despite an even greater resistance than they encountered in the morning, double the number of bombs were dropped, and all our machines succeeded in returning.

Hardly less significant to Germany is the skill with which the bombing of these towns is being carried out. The courage and ambition of the average German aerial bomber does not seem to carry him beyond the perfectly promiscuous bombing of towns, except perhaps when he locates a big American or English hospital far from the battle line, then he will descend from his safe height, and having bombed the building, will adventurously expose himself to a chance rifle or revolver bullet, while machine gunning the doctors, nurses and orderlies as

they are trying to carry their patients into shelter.

The Royal Air Force is singularly different in its tactics, and confines itself to important and legitimate military objectives, invariably descending low enough to make a certainty of inflicting genuine military damage. For example, to take at hazard a specimen page of R. A. F. aerial photographs we find the indisputable camera record of the following bomb bursts:

OBENDORF—3 bursts, one on the railway sidings, one alongside the extensions of the Stauer Works, one on the Auser Works.

OFFENBURG—3 bursts, two beside the railway work shops, one on station.

OFFENBURG (following day)—5 bursts, one on main station, two on railway, one direct hit on railway bridge, one on railway south of the station.

Facts such as these go far to explain the intense resentment which Germany feels with regard to the now incessant attacks upon her centers of munitions production, attacks which not only cause her grave military damage and delay, but compel her to detach a large and growing number of machines for the defense of the threatened centers.

#### Growth of Cleveland Plants

CLEVELAND, Sept. 10—As an indication of the continued development of the automobile and allied industry in this section, building permits issued in Cleveland during 1917 offer interesting figures. The following are some of the important permits granted to concerns manufacturing automobile products:

Cleveland Welding & Mfg. Co. ....	\$50,000
Cleveland Welding & Mfg. Co. ....	40,000
Warner & Swasey Co. ....	60,000
American Steel & Wire Co. ....	25,000
Park Drop Forge Co. ....	60,000
Park Drop Forge Co. ....	36,000
Grant Motor Car Corp. ....	65,000
U. S. Tool Co. ....	25,000
Lang Body Co. ....	75,000
Parrish & Bingham Co. ....	80,000
Hydraulic Pressed Steel Co. ....	30,000
Hydraulic Pressed Steel Co. ....	300,000

#### Work of Highways Transport Committee

WASHINGTON, Sept. 10—The work of the Highways Transport Committee, Council of National Defense, this committee having been appointed to make the most effective use possible of the highways as one of the means of strengthening the nation's transportation resources, is now being developed in such a way as to take in every state in the Union. Further, through the medium of State Highways Transport bodies, functioning with the national body, this organization is being developed in some states not only down to the districts but to the counties and even communities.

The State Highways Transport bodies are a part of the State Council of Defense. They consist of the following:

The chairman of the State Highways Transport Committee, five members of the Highways Transport body and a secretary.

The five members in question are named to represent areas of varying sizes and populations, each of the five mem-

bers being chosen from one of such five different areas, and in turn serving as chairman of his district committee. The district boundaries are laid out in harmony with existing conditions, the aim being that the most effective results possible may be brought about. For instance, in one locality large population centers may be found to be best as the heart of one or more districts. Again, in other sections, where cities of large population are not found, the district boundaries may be made to embrace agriculture, lumber, oil or other areas.

#### Milwaukee-Chicago Motor Truck Line

MILWAUKEE, WIS., Sept. 10—The first regular freight service by motor truck to be established between Milwaukee and Chicago was opened during the past week by the Motor Transportation Co. of Milwaukee, organized with a capital stock of \$100,000 by Milwaukee capital and Charles C. Newburn, of Chicago. Four trucks, each of 3-ton capacity, are now being operated over the 90-mile route. Besides the terminal offices in Milwaukee and Chicago, the company will maintain stations at South Milwaukee, Racine, Kenosha and Waukegan for the handling of freight. The Milwaukee interests in the new company are represented by Charles A. Robinson and George D. Persons, formerly passenger engineers on the Milwaukee road. During the first few days of the operation of the new service no difficulty has been encountered in getting capacity loads, going and returning. In fact, much more freight has been offered than can be carried with the present equipment of four trucks, and the promoters expect to add as many more within a short time.

#### Carload of Fordsons Sent to Mexico

DEARBORN, MICH., Sept. 10—Henry Ford & Son received a visit last week from Randolph Robertson, vice-consul of the United States, who came from Monterey, Mexico, to make arrangements with the plant to have a carload of tractors sent down to that country. This carload, with the two tractors sent recently to President Carranza, makes a total of nine Fordsons that will soon be doing work on Mexican soil.

Two expert men are being sent to Mexico to give demonstrations with a view of educating the natives in modern methods of agriculture. The carload of tractors has been sold to Mexico at the fixed factory price, viz., \$750.

Owing to the shortage of pig iron and chrome nickel steel, the production of the plant has dropped slightly during the last week. Only 803 machines were produced as against 919 the week previous. The average daily production now is 125 to 130.

Plans for the new plant at Hamilton, Ohio, have been drawn and are now awaiting the O.K. of C. E. Sorenson, manager of the company, who will soon go to that town to start building activities.

## Flying "Stunts" Are Vitally Important

Essential That Military Aviators Be Taught Every Trick of the Trade—Successful Flier Must Be Able to Surpass Opponent in Skill

WASHINGTON, Sept. 10—Flying stunts are vitally important if the flier is to be victorious in combat with the enemy, according to statements made here by British air authorities. The lives that are lost in teaching stunts in training are but few in comparison to those that would be lost if the fliers were sent against the Boche without stunt practice.

"Not every one realizes," say the British authorities, "what a long time it takes to make a service flier. The average period from the time the pupil is brought to the Cadet Schools of the Royal Air Force to the time he is ready to go overseas and fly over the lines is about 7 months; yet the actual training in flying is one of the simplest items.

"The principal factor to consider in teaching flying in war time is whether it is worth while to spend the necessary time on a pupil.

"If a country is at peace, and there are plenty of machines available, it may pay to stick to a man who will undoubtedly make a flier sooner or later, for any one can fly if sufficient time be given to his instruction. But in times of war, as at the present time, when we have neither a surplus of machines available for flying nor the extra time to spend in training, it is not a practical thing to do.

#### Specialized Training Essential

"The hard specialized training which every one has to come to sooner or later is not only important, it is absolutely essential.

"Much has been said about 'dangerous stunts,' with the implication that these are spectacular performances which thrill the spectators but are needlessly risky, and I think this needs a little explanation.

"It is quite true that some lives were lost in the earlier days in instructing pupils in what we call 'stunting,' but it is quite useless to send a man overseas if he is unable to 'stunt.'

"In individual fighting, unless the flier can really do things better than the German, he is not going to come out alive, and it is no earthly use imagining that when the crucial moment arrives stunting is going to come naturally. For instance, when one machine meets another, each speeds up and goes through every kind of maneuver to get into a good position so as to be able to 'get' his opponent. The man who is going to come out alive is the man who can outdo his opponent in flying. It is not a question of 'getting away from the German.' It is not a matter of getting away at all, but of getting into a good position so that you can down him.

"He is going to do the same thing, and unless you are able to outdo him in his

maneuver you are going to come out beaten; and unless you are trained to do real stunts (which are really not at all dangerous) you are not going to be able to down him. The danger is not in 'stunting,' but in not being able to 'stunt.'

"If a flier goes overseas, and is not able to do these things, then his life is not worth a cent. If he can do these things, and the time comes when he is absolutely face to face with his opponent, the man who will kill his opponent is the one who can throw his machine about the most and get out of a difficult position. Getting out of the difficult position saves his life, but this is not all; the real problem is to get into a good position so that he can down the enemy, and the downing of the Boche is the thing that every flier is out for. He is not there to get away, he is there to kill his opponent.

#### Flier Must Be Properly Trained

"To succeed, the flier must be taught properly. It may cost one or two lives this side of the water, but if the men are taught thoroughly it will mean the ending of these casualties on the other side, and the causing of many more to the enemy.

"What is more, if the pilot does not know how to 'stunt,' it will not only mean the death of the pilot himself, which is relatively not so important in view of the fact that so many thousands of men have been killed in the war, but it may result disastrously to a great number of men on the ground. When the man in the air goes down, there may be batteries dependent upon him for spotting our own fire and the enemy's artillery; there may be infantry regiments waiting to know where the Germans are, and there may be whole divisions waiting for certain information.

"It is thus absolutely criminal to send a pilot to the front who does not know how to fly, and the only way to make him capable is to teach him to 'stunt.'"

#### Willys-Overland to Have Barracks

TOLEDO, OHIO, Sept. 10—The government is preparing to handle the labor supply for munition manufacture in the Willys-Overland plant. Plans have been completed for the first unit of a cantonment to house laborers, just north of the factory. The buildings will be similar to those at the army cantonments. The first one will furnish temporary sleeping quarters for 200 and will contain a mess hall.

#### Lober Radiator Enlarges Capacity

TOLEDO, Sept. 7—The Lober Art Brass & Specialty Co. has leased adjoining rooms and will double the floor space and capacity of its plant. New equipment is being installed.

## Passenger Car Prices Going Up

Eight Makers Boost Lists Substantially—Truck Prices, Too, Advanced

DETROIT, Sept. 5—The Willys-Overland Co., Toledo, has increased the prices of all its models, effective Sept. 1, as follows:

Model	Old Price	New Price
90 (T) Touring.....	\$895	\$1095
90 (R) Roadster.....	895	1095
90 Country Club.....	925	1145
90 Sedan.....	1385	1665
90 Panel Delivery.....	895	1045
90 Express Delivery.....	875	1025
1200-lb. Express Delivery	1075	1150
1200-lb. Spec. Open Panel		
Delivery, right-hand		
drive.....	1075	1150
85-4 Touring.....	1025	1175

### Cadillac Prices Increase

DETROIT, Sept. 5—The Cadillac Motor Car Co. has advanced its prices \$300 on the following models, effective Sept. 1:

Model	New Price	Old Price
Touring Car.....	\$3520	\$3220
Phaeton.....	3520	3220
Roadster.....	3520	3220
Brougham.....	4390	4090
Suburban.....	4640	4340
Limousine.....	4695	4395
Landaulet.....	4795	4495
Town Limousine.....	4660	4330
Town Landaulet.....	4810	4510

F. O. B. Detroit, not including war tax.

### Nash Prices Go Up

KENOSHA, WIS., Sept. 10—The Nash Motors Co. increased the price of its cars and trucks on Sept. 1 as follows:

	New Price	Old Price
5-pass. touring.....	\$1490	\$1395
7-pass. touring.....	1640	1545
4-pass. roadster.....	1490	1395
6-pass. sedan.....	2250	2085
4-pass. coupe.....	2250	2085
1-ton chassis.....	1650	1595
2-ton chassis.....	2175	2075

### Kissel Prices Revised

HARTFORD, WIS., Sept. 10—The Kissel Motor Car Co. has increased the price of its cars and trucks as follows:

	New Price	Old Price
4-pass. roadster.....	\$1743	\$1645
4-pass. sedan.....	2293	2195
5-pass. touring.....	1743	1645
5-pass. sedan.....	2293	2195

#### Trucks

	New Price	Old Price
General Utility, 2-ton....	\$2073	\$1885
Freighter, 2½-ton.....	2832	2575
Heavy Duty, 4½-ton.....	3905	3550
Dreadnaught, 6-ton.....	4785	4350

### Jones Car Prices Advanced

WICHITA, Sept. 7—The Jones Motor Car Co. has advanced its prices as from Sept. 1 as follows:

	New Price	Old Price
27-B 7-pass.....	\$2100	\$1875
Sport. 4-pass.....	2350	....

Several minor refinements have been incorporated in the 7-passenger model and the 4-passenger sport model is fitted with wire wheels, 32 x 4½ in. cord tires and paint and upholstery colors are optional.

### Hupp Prices Advance

DETROIT, Sept. 10—The new price of both the Hupmobile touring car and roadster is \$1,500 instead of \$1,350. This advance was effective Sept. 1.

### Packard Prices Increase \$500

DETROIT, Sept. 10—The Packard Motor Car Co. has advanced its prices, effective Aug. 26, as follows:

Model	New Price	Old Price
3-25 Touring.....	\$4,800	\$4,300
3-25 Limousine.....	6,350	5,850
3-25 Brougham.....	6,500	6,000
3-25 Coupe.....	6,150	5,650
3-35 Touring.....	5,150	4,650
3-35 Limousine.....	6,700	6,200

### Hudson Super-Six's Advance \$250

DETROIT, Sept. 10—The Hudson Motor Car Co. has advanced the prices of the Super-Six models, \$250, effective Sept. 1, as follows:

Model	New Price	Old Price
Seven-pass. Phaeton.....	\$2,200	\$1,950
Four-pass. Phaeton.....	2,300	2,050
Sedan.....	3,000	2,750
Runabout Landau.....	2,690	2,440
Limousine.....	3,650	3,400
Town Car.....	3,650	3,400
Coupe.....	3,100	2,850
Town Limousine.....	3,400	3,150

### Motor Transport Corps to Consist of 154,774 Men

(Continued from page 470)

Transport Corps is operating 1500 trucks in convoy trains in this country exclusive of the trucks used at the various army posts. These 1500 trucks carry various kinds of merchandise and munitions for the army over an average of 100,000 miles every 24 hr. The Motor Transport Corps is desirous of securing a great number of men and officers, men especially qualified to drive motor vehicles by the thousand, and executives with business experience are wanted for officers. Men in the deferred classes of the first draft will be inducted into this service. Further information can be secured by addressing the chief of the Motor Transport Corps, Washington, D. C.

There is quite a difference of opinion here as regards the re-establishment of the original A and AA standard trucks in the army program. Members of the Motor Transport Corps state that it is most improbable, while on the other hand several consider it a possibility. It is also stated by members of the Purchasing Section that the report of contracts placed for 17,000 A trucks, which was given out by an officer of the Motor Transport Corps, is incorrect and that only a small part of this business has been confirmed.

### To Enlarge Selfridge Field

WASHINGTON, Sept. 10—Eighteen hundred acres of land adjoining Selfridge Field, Mt. Clemens, Mich., have been acquired and will be added to the field for aviation instruction purposes.

## Industries Must Use More Women

H. E. Miles Says 500,000 More Skilled Workers Will Be Needed in 90 Days

CHICAGO, Sept. 10—American industry is not as yet at war and it is time that it were. It does not realize that 2,000,000 men will be taken from the industries of the United States within a few months, and that it will take 12,000,000 people to produce what these 2,000,000 consume. This is the way in which H. E. Miles, chairman Section on Industrial Training for the War Emergency Advisory Commission, Council of National Defense, aroused the Employment Managers' Association of Chicago at its dinner last night.

Mr. Miles' work is seeing that training courses for unskilled labor are installed in industries. His plan, which is the plan of the Government, is to install practical training courses in the larger factories for the development of semi-skilled employees.

In emphasizing the need for skilled labor, Mr. Miles said that within 90 days over 500,000 new skilled laborers will be needed for manufacturing operations. This is more than the total of skilled mechanics in the whole country in 1910. The production of our factories must be doubled. So imperative is the need that Mr. Miles asked in the name of the Government that the Chicago employers act to-morrow in the establishment of these schools. In illustrating what could be done the speaker told of the results of similar schools in England, and stated that European factories are getting out a much greater per capita production since the war and a 25 per cent increase in per capita production is expected in America.

England's original method at the beginning of the war consisted of taking 60 schools from which they discharged the teachers and installed shop foremen, etc., as instructors. By this means, however, they got only two thousand new skilled laborers a month. They undertook to train thousands of women not only in the schools but in the factories themselves in separate instruction bays. English employers set up human tool-rooms in each factory. France is doing the same thing and requires every plant employing 300 people or more to put in training schools. In England it is made as a part of the ordnance contract.

Mr. Miles insists that American plants must use more women and must depend on women chiefly for their skilled labor.

"Sex has nothing to do with machine production," said Mr. Miles. He stated that there is nothing on an airplane that women are not doing in England. The Curtiss company here is training women for skilled operation in four days. The Wolwich Arsenal in England has 40,000 women in it.

The best method of training, said Mr. Miles, is to take men from the factory

who can tell what they know, send them to schools and make them high class instructors, then send the women, old men and boys for a short period of intensive training on some particular job.

As a rule these schools are not an operating expense, as the material they turn out is production material, and the rate of pay during training is low enough so that the unit cost is not higher than that of the regular production part of the plant. Some of the plants in this country pay 20 to 30 cents an hour while training on work that pays 45 cents an hour in production.

E. A. Russell, chief ordnance inspector, added that with 4,000,000 men on the other side next year the army program would call for \$14,000,000,000 worth of material. He said that the shells already contracted for in America if placed end to end would reach around the earth at the equator and then overlap for 5000 miles.

#### Passenger Car Pledge

WASHINGTON, Sept. 10—No special priority class rating has been assigned to the passenger car industry and it will be necessary for each manufacturer to make application for the steel he requires. The preference in priority will be graded, possibly, by the class of steel required. A "passenger automobile manufacturer's pledge" has been approved by the War Industries Board and must be filled in by every manufacturer who desires to secure steel and filed with the Automotive Section of the Board. After the pledges have been signed and sent in, the manufacturer may make application to the Director of Steel Supply, War Industries Board, Washington, for a permit to purchase the steel or manufactured steel products.

The manufacturer's pledge is as follows:

War Industries Board,  
Washington, D. C.

Gentlemen:

Attention: Automotive Products Section  
The undersigned hereby pledges itself:

- (1) Not to purchase iron or steel or iron or steel parts or equipment except under permit from the Director of Steel Supply.
- (2) To limit its purchase of materials, parts, equipment and supplies to an amount which does not exceed either
  - (a) The amount absolutely necessary to match up its stocks now on hand, or
  - (b) The amount necessary to permit a production of passenger automobiles and all repair parts therefor for the six months ending Dec. 31, 1918, not in excess of 25 per cent of its production for the calendar year 1917.
- (3) That it will conserve and economize in every possible way its stocks of iron and steel and their products now in its hands, or that may come into its possession, and will release on request of the War Industries Board to such other manufacturer of passenger automobiles as may be designated by the said board such of its stocks as can be utilized by such other manufacturers and which are not required by it for either the limited production above specified or for war work.
- (4) That it will from time to time render such reports of its activities under oath or otherwise as may be called for by the War Industries Board.

## Ford Stops Building Passenger Cars

Company to Devote Entire Plant to War Work—Franklin and Hudson Quit, Too

DETROIT, Sept. 10—The Ford Motor Co. will immediately abandon the manufacture of passenger cars during the period of the war; only a limited number will be made for the use of the Government. From this time forward the entire resources of the company are to be devoted to war work. The Ford plant will be used exclusively for the production of Liberty engines, tanks, ambulances and such other work as the Government may desire.

Ford is the third manufacturer to announce a policy of 100 per cent war work. The Hudson Motor Car Co. already has let it be known that henceforth and until after the war no more Hudson cars will be produced. This week the Franklin Automobile Co., Syracuse, has made public that its plants are now practically 100 per cent on war work and that it is the intention not to produce any more Franklins until after the war.

The decision to devote the entire Ford resources to war work applies also to the 31 branch assembly plants scattered throughout the large industrial centers of the country. Six of these, located in Cambridge, Mass.; Louisville, Ky.; Philadelphia, St. Louis, Washington and Long Island City, already have been turned over entirely to the Government and the others will be turned over rapidly.

Abandonment of the manufacture of passenger cars will not affect the production of trucks and tractors. Trucks are considered essential by the War Industries Board, and their production will be continued. The Fordson tractor is produced by Henry Ford & Son in an entirely separate plant at Dearborn, Mich., and its production will be continued.

The conversion of the Ford passenger car production facilities to 100 per cent war work has not been entirely unexpected. As long ago as November there were persistent rumors that the manufacture of passenger vehicles was to be eliminated. These, however, were denied at that time.

Immediately following the denial of these rumors, announcement was made from the Ford plant that the top notch in production had been reached, the factory having turned out a total of 3000 cars on Nov. 23.

This production was maintained practically constant until early in February when it was cut down 50 per cent and remained practically constant until nearly the end of June. At that time the production had been further reduced to 750 cars a day.

Beginning Aug. 1 production was further reduced to 350 passenger cars a day. The production of trucks has been steadily increasing, until at the present time approximately 400 are being turned out daily.

During the fiscal year ending July 31 last the production of the Ford Motor Co. totalled approximately 700,000 cars as compared with 785,000 during the last year. On June 10 there were unfilled orders on hand for more than 110,000 cars.

#### Owen Develops Farm Light System

NEW YORK, Sept. 10—A farm lighting system completely automatic in operation has been placed on the market by R. M. Owen & Co., 1765 Broadway, New York. It comprises a single cylinder 8 x 4-in. water-cooled vertical engine direct-connected to a four-pole generator of 1250 watts output. Engine speed is controlled by a centrifugal governor acting on the throttle valve, and a constant voltage is maintained by the use of compound field windings.

Included in the outfit is a 16-cell, 80-ampere-hour Willard battery in glass jars. The outfit is started by pushing a button switch and stopped by pushing similar switch. When once started the engine runs until the battery is full, when it is automatically shut off. When the battery has been discharged to a certain predetermined state the engine is automatically started.

#### Packard 100 Per Cent On War Work

DETROIT, Sept. 12—Packard starts Thursday 100 per cent on war work. Packard will confine its efforts to the production of Liberty engines, of which it is now making about 35 daily, airplane bodies, war tractors and trucks.

There are several airplane body models one of which is an entirely new one the French Commission is working on. There have been some completed which are now in use in tests at Dayton and elsewhere.

Sensing the placing of an order for Liberty engines from the government the company stimulate the production of Twin Six power plants and was fortunate in producing 6000 before the first order for 600 Liberty engines was placed. The production of trucks includes all war models and those for commercial use which are intended for essential industries. The truck production schedule provides for 8000 to 10,000 vehicles for the fiscal year ending Sept., 1919. Fully one hundred million dollars worth of war work will have been completed during the coming year.

Twelve thousand men and women are employed by the company in the sixty-one buildings which cover fifty-six acres of ground.

During the suspension of car manufacture the company will endeavor to maintain service on all trucks and the forty-five thousand passenger cars that are now running.

The company has affiliated with it 110 dealers who will be affected by the new arrangement; many of these have increased their stocks of accessories. Those who are handling trucks will be permitted to continue, provided they sell the vehicles to essential industries.

**Horowitz in Charge of Tanks**

WASHINGTON, Sept. 6—Louis J. Horowitz, formerly president of the Thompson Starrett Construction Co., New York, has been appointed assistant chief of ordnance, in charge of tanks. Mr. Horowitz will have complete authority on the engineering, manufacturing and inspection of tanks.

Brig.-Gen. J. T. Thompson, U. S. A., retired, has been made director of ordnance training, and will work out the types of training to be given the personnel of the Ordnance Department, and will make provisions for this training. Capt. S. E. Blunt has been appointed employment supervisor in charge of the personnel employment bureaus of the several arsenals and other ordnance establishments.

H. E. Henry has been appointed general sales manager of the Fulflo Pump Co., Blanchester, Ohio, succeeding A. N. Martin, who has accepted a position with the Pyle National Co., Chicago.

Thos. J. Little, Jr., engineer of the Lincoln Motor Co., Detroit, has been appointed a member of the welding research committee of the Emergency Fleet Corp., United States Shipping Board.

W. G. Bell, for the past 4 years assistant sales manager in the Dominion of Canda for the Studebaker Corp., has been appointed Canadian sales manager of the Cleveland Tractor Co., Cleveland.

William B. Stout has resigned his position as technical adviser to the Aircraft Board at Washington and has returned to Detroit to take up the manufacture of a plane of his own design. The experimental work and preliminary construction is being carried out by W. C. Rands, of the Rands Mfg. Co., Detroit.

J. H. Fenton of the Los Angeles office, of the Westinghouse Electric & Mfg. Co. has recently been appointed manager of the Industrial Division of that office, which includes jurisdiction over the Tucson and El Paso offices.

J. N. Mahoney, for 12 years a member of the Engineering Department, has tendered his resignation from the Westinghouse Electric & Mfg. Co. to open consulting offices in New York.

B. F. Page, formerly eastern representative of the Four Wheel Drive Auto Co., Clintonville, Wis., has been appointed assistant to L. P. Fortin, acting manager of the Oneida Motor Truck Co., Green Bay, Wis.

E. J. Wright, formerly with the Allen Motor Car Co. has been appointed assistant to the sales manager of the Dort Motor Car Co., Flint.

Ralph J. Handy, former distributor of the Tonford truck attachments in Detroit, has become sales manager of the Laiton Truck Co., Youngstown, Ohio.

## Men of the Industry

### *Changes in Personnel and Position*

John Squires has resigned as general manager and chief engineer of the Signal Motor Truck Co., Detroit, his duties as manager being taken up by F. W. Henderson, and those of chief engineer by S. Deutsch. Mr. Squires will shortly announce his plans for the future.

W. C. Anderson, manager of the Ford Motor Co. assembling plant at St. Louis, has been transferred to Chicago following the turning over of the St. Louis building to the quartermaster's department of the United States Army. He will have charge of assembling plant in Chicago for the present.

Charles E. Becker, formerly advertising manager of the Jones Motor Car Co., Wichita, Kan., has been called to the colors.

A. B. Jones, second vice-president of the B. F. Goodrich Co., Akron, has been appointed by the American Red Cross to the post of director of transportation and distribution of Red Cross supplies in France.

Frank M. Eldredge, Detroit, has assumed entire charge of the sales and advertising departments for L. V. Flechter & Co., New York. He has been handling all the national advertising for the company for the past year and will now add the sales to his other duties. He will continue his publicity and sales promotion bureau.

C. W. Whitson, formerly with the Fulton Motor Truck, Farmington, Long Island, and who recently resigned from that organization, has been appointed general sales manager of the Panhard Motors Corp., Grand Haven, Mich.

A. W. Redlin, for the past 2 years division superintendent of the Mitchell Motors Co., Racine, has been appointed assistant works manager of the Erd Motor Co., Saginaw.

L. F. Collins has been appointed truck sales manager of the Nash Motors Co. This position was left vacant by H. C. Hart, who recently received a captain's commission in the Ordnance Department of the United States Army.

**Mor: Money for Kelly Men**

CLEVELAND, Sept. 9—The Kelly Resmer Co. has voluntarily increased the wages of its employees ten per cent beginning August 24. The increase was unsolicited.

**Appoint Fordson Export Distributer**

DEARBORN, MICH., Sept. 6—Henry Ford & Son, Inc., have appointed Sherman & Sheppard as export distributors of Fordson tractors. This firm has a New York office and will also have one in Buenos Aires.

**Urge Bankhead National Highway**

WASHINGTON, Sept. 10—Delegations representing chambers of commerce from Richmond, Va.; Atlanta, Ga.; Memphis, Tenn.; Dallas, Tex.; Oklahoma City and other southern and western cities will meet in Washington Dec. 10 to urge upon Congress the necessity of the Bankhead National Highway from Washington to Los Angeles. The meeting will probably be in the form of a joint hearing with Senators and Congressmen, and the establishment of the road will be urged as a war measure. It was pointed out that the highway traverses 22 cantonments, aviation and military posts.

**Anthracite Production Gains Slightly**

WASHINGTON, Sept. 10—Bituminous coal production for the week ended Aug. 31 was 12,642,000 tons, approximately the same as the preceding week. Anthracite production for the week was 2,259,716 tons, an increase of 125,716 tons or 5.9 per cent over the preceding week.

During the week of Aug. 24 the bituminous mines operated 81.5 per cent of their full time output. Production losses were due to car shortage, 9.9 per cent; labor shortage, 3.5 per cent; mine disability, 3.9 per cent; no market, 0.4 per cent; all other causes, 0.8 per cent.

**254,722 Cars in Michigan**

LANSING, Sept. 9—On Sept. 1, 1918, there were 254,722 automobiles in the State of Michigan, according to the Secretary of State. The registration records also show that of the 254,722, 229,762 were passenger cars and 24,960 were commercial vehicles. The number of motorcycles registered was 7452 and there were also 22,648 chauffeurs on Sept. 1. The total fees collected up to Sept. 1 is \$2,840,995.35.

**Chicago Pneumatic Enlarges**

CLEVELAND, Sept. 9—The Chicago Pneumatic Tool Co., Chicago, will erect a \$150,000 addition to its plant, in order to double its present capacity. Work on the building will be completed about Nov. 1.

The Cleveland Twist Drill Co. will also erect a \$120,000 addition to its factory.

**Car Makers Want Tools**

DETROIT, Sept. 9—The Maxwell Motors Corp. is inquiring for a large number of tools for shell-making. The Winston Motor Car Co., Cleveland, is in the market for screw and milling machines as well as drill presses. It recently obtained a large order for tripods for Browning machine guns.

**Electric Steel Absorbs Crucible**

CLEVELAND, Sept. 7—The Electric Steel & Forge Co. has absorbed the Crucible Steel Forge Co. of this city and will continue and expand this business. For this purpose it will purchase adjoining land on which to erect suitable buildings, install two electric furnace units, heat-treating furnaces, rolling mills, machinshop and other necessary equipment. It will have a production capacity of 9000 to 10,000 tons per annum of tool steel and alloy steel, and a rolling and forging capacity in excess of this tonnage.

The products of the company will include carbon and tungsten tool steel, nickel, vanadium, chrome, chrome-vanadium, chrome-nickel, silicon-manganese and other kinds of tool steel and special alloy steel. Among its specialties, besides billets and bars for the market, will be heat-treated piston rods, die blocks and rings, gun forgings, gun mount forgings, spindles, gear rings, blanks and shafts.

The officers of the company are: President, James H. Foster, president and general manager of the Hydraulic Pressed Steel Co.; vice-president and general manager, D. W. Wells, formerly general manager of the Crucible Steel & Forge Co.; secretary, C. R. Cross, president of the Colonial Savings & Loan Co.; treasurer, A. B. Smythe, president the A. B. Smythe Co. The board of directors is composed of the officers and the following: C. R. Hamilton, director Cleveland Brass & Copper Mills, Inc.; Harnes Herron, consulting metallurgist the Cleveland Engineer Society; J. A. House; W. D. Sayle, president the Cleveland Punch & Shear Works Co.; W. H. Staring, vice-president and general manager the Peerless Motor Car Co.

**Wisconsin Schedules Tractor "Rally"**

MILWAUKEE, Sept. 9—The Wisconsin Power Farming Association, organized recently at Milwaukee by manufacturers and distributors of farm tractors and power farm machinery, will hold a "tractor rally" at the Republican House, Milwaukee, on Friday evening, Sept. 13, to acquaint dealers and owners of such equipment with its plans to guarantee every owner proper service after he has been sold. The meeting is held at this time to take advantage of the presence of many dealers and owners attending the Wisconsin State Fair, which closes on Saturday. During the fair the association is making an energetic campaign for new members among the thirty-six tractor manufacturers represented on the grounds.

**Northern Foundry to Double Plant**

MARINETTE, WIS., Sept. 8—The Northern Foundry Co., organized early this year by Marinette, Milwaukee and Racine capital to engage in the manufacture of automotive and agricultural castings, has concluded arrangements to double the size of its plant by taking over adjoining buildings. The present

**Current News of  
Factories***Notes of New Plants—Old  
Ones Enlarged*

force of 60 will be increased to 125 or more by the end of September. Much of the output is being taken under contract by the J. I. Case T. M. Co., Racine, Wis., maker of passenger cars, tractors and other power farm machinery. J. M. Fitzpatrick is manager of the Marinette foundry.

**Puritan Gets Alco**

DETROIT, Sept. 6—The Puritan Machine Co. has completed arrangements with the American Locomotive Co. covering the purchase of the entire service repair parts business, including the existing stock of spare parts, tools, jigs, dies, blueprints, etc., covering the Alco passenger cars and trucks formerly manufactured in Providence, R. I. The service business will be continued from the Providence plant for the present.

**New Plant for Wells Mfg. Co.**

FOND DU LAC, WIS., Sept. 9—The Wells Mfg. Co., Fond du Lac, Wis., manufacturing electric lighting units and other accessories for motor vehicles and similar purposes, has moved its plant into new quarters, consisting of a two-story fireproof building, 50 x 120 ft. in size, which makes available considerably more floorspace than in its former works. The company is extensively engaged in Government contracts, the nature of which is not disclosed.

**More Room for Highway Trailer**

EDGERTON, WIS., Sept. 9—The Highway Trailer Co., Edgerton, Wis., has started work on a large factory addition, 40 x 200, one and two stories high, to provide the additional facilities required to adequately handle large Government orders for trailers for hauling ordnance, munitions, aircraft, etc. About \$30,000 will be invested in the improvement. James W. Menhall is general manager.

**Buick Starts on Two New Units**

FLINT, Sept. 3—The Buick Motor Co. will erect two new factory buildings to aid in Liberty engine production. One is a two-story structure, 80 by 240, to cost \$77,760, to take care of the overflow production of the eight-cylinder Liberty engine from Plant No. 11. The contract calls for completion by Nov. 1. The other is a two-story aluminum foundry, 120 by 300, in which will be the melting room, molding floor and core room, and a front building, 90 by 240 ft., in which the cleaning and sand-mixing rooms are to be located. The estimated cost of the latter is \$163,500.

**Wisconsin Duplex Becomes Oshkosh**

OSHKOSH, Sept. 9—The Wisconsin Duplex Automobile Co., Oshkosh, Wis., which recently completed development work and is now engaged in a regular production of commercial chassis, has changed its corporate style to the Oshkosh Motor Truck Mfg. Co. and adopted the trade-mark of "Oshkosh" for its product. The principal object of the change is to give due recognition to the city where the truck is being made, and also to avoid confusion with existing concerns which include the word "duplex" in their corporate names. It is planned to manufacture from sixty to seventy-five trucks for delivery by Jan. 1. The first five cars of the initial commercial output will be ready during the coming week, and most of them will go to purchasers in and around Oshkosh. A sales organization is now being perfected and the company plans to undertake an extensive advertising campaign.

**New Method of Obtaining Brinell  
Hardness***(Continued from page 457)*

As in the case of the standard Brinell machine, there are certain limitations to all ball hardness testers. In those cases in which the metal is extremely hard a permanent deformation of the ball results. Where the test specimen is soft, the ball penetrates so closely to the supporting surface or anvil that the hardness of the latter affects the results. Small narrow specimens of hard steel crack under test, and soft narrow ones permit of an easy lateral flow which affects the accuracy of the test. Fortunately, with the exception of thin pieces such as sheets, none of the above cases are so extremely common as to materially curtail the use of the Brinell machine. In the case of thin soft sheets, by reducing the load to 1000 kg. or by reducing the size of the ball consistent results can be obtained; with the device described it is necessary to use a smaller ball and less impact.

**Two Varying Factors**

In the standard Brinell machine there are only two factors which can be varied, namely, the load and the size of ball. In the device described the weight, the height and the diameter of the ball may be varied. Just what values will eventually be assigned to these factors has not as yet been determined.

In designing a machine upon the principle described, it is possible to have it either hand or power operated. The weight can be raised and tripped at as rapid a rate as the samples can be supplied and removed, so that it will work if required with the regularity of a shear or punch press. The cost of manufacture will be less than that of the standard Brinell machine, since there are fewer accurately machined parts required, and this, together with the rapidity with which tests can be made, should, in the writer's opinion, create a useful field for a device of this nature.

## Process Refining System Would Increase Gasoline Production

(Continued from page 447)

taken up process systems as they should. It is estimated that of the 75,000,000 barrels of crude oil which go to the refineries each year for gasoline manufacture, not over 15,000,000 barrels are distilled by process systems.

Some experts familiar with the oil refinery field declare that many of the oil refiners are narrow-minded on this process system of production and do not seem willing to take up process systems in use by other companies, which can be done on a royalty basis. Recently the Standard Oil Co. offered the Burton process free to other refineries for the period of the war but this was not attractive because it called for large installation by these refineries, which installation would be useless after the war unless under a royalty basis with the Standard Oil Co. There are, however, other processes not taken up by the large companies which have demonstrated that they are practically as efficient as those processes now in extensive use.

The Fuel Administration should give some attention to more rapid introduction of the process systems rather than focusing its attention too much on the curtailment method, which seems the only one up for consideration at present.

The necessary expenditure for installing a process system is not prohibitive; estimates made by men who have spent a lifetime in the refining field declare that it is possible to pay off the cost of the installation of a process system in 3 months. The figures they give are as follows:

It will cost from \$80,000 to \$120,000 to construct a process plant that will refine 1000 bbl. per day.

The profits that will come from this process plant as compared with the skimming plant are estimated as follows by these experts:

By the skimming method the refinery earns on an average of 60 cents per bbl. Sometimes the profit is as low as 35 cents and at other times it rises to 75 cents.

By installing a process system these profits are increased from 60 cents to \$1.75 per bbl., or a profit of approximately \$1.15 per bbl. additional by the process system.

Estimating roughly on an added profit of \$1 per barrel, the process system installation which will handle 1000 bbl. per day would give an added profit of \$1,000 per day, and in 80 days would show a profit equal to the cost of installing the best systems.

Under the skimming system of gasoline refining a barrel of crude oil which reaches the refinery is broken up approximately as follows:

Gasoline .....	25 per cent
Light oil .....	8 per cent
Fuel oil .....	67 per cent

Under the process system the refining of this same gallon of crude will yield as follows:

Gasoline .....	50 per cent
Fuel oil .....	47 per cent
Losses .....	3 per cent

In view of these figures it would seem of importance that steps be taken to conserve our supply of crude oil and incidentally our supply of gasoline by insisting upon process installation. In the present war this seems just as important as conserving our food supply by calling for various mixtures of grains as suggested by the Food Administrator. The advice of the Food Administrator has not been to curtail except beneficial to the human being but rather eat according to the suggested combinations of food.

## Preference List of 74 Industries

(Continued from page 471)

principally in rolling and drawing copper, brass and other copper alloys in sheets, rods, wires and tubes)..... II

Chain (plants making principally iron and steel chains)..... III

Chemicals (plants making same for aircraft and war needs)..... I

Chemicals (other chemical plants)..... IV

Coke (plants engaged in producing metallurgical coke and by-products, including toluol)..... I

Electrical equipment (plants engaged principally in manufacturing same)..... III

Farm implements (plants engaged principally in manufacturing farm operating equipment and agricultural implements)..... IV

Ferro-alloys (plants engaged principally in producing ferro-chrome, ferro-manganese, ferro-molybdenum, ferro-silicon, ferro-tungsten, ferro-uranium, ferro-vanadium and ferro-zirconium)..... II

Machine tools (plants principally making same)..... II

Mines (coal)..... I

Mines (producing metals and ferro-alloy minerals)..... II

Mines (plants making principally mine tools and equipment)..... III

Oil and gas (plants engaged principally in producing oil and natural gas for fuel or for mechanical purposes, including refining or manufacturing oil for fuel or mechanical purposes)..... I

Oil and gas (pipe lines and pumping stations engaged in transporting oil and natural gas)..... I

Oil and gas (plants engaged principally

in manufacturing equipment or supplies for producing or transporting oil or natural gas or for refining and manufacturing oil for fuel or mechanical purposes)..... III

Steel making furnaces (plants engaged solely in manufacturing ingots and steel castings by the open hearth, Bessemer, crucible or electric furnace processes, including blooming mills, billet mills and slabbing mills for same)..... I

Steel (plate mills)..... I

Steel (all plants operating steel rolling and drawing mills exclusive of those taking higher classification)..... III

Tanners and tanning (all plants engaged principally in tanning leather or in manufacturing tanning extracts)..... IV

Textiles (plants engaged principally in making textile machinery, cotton or woolen textiles, or cotton or woolen knit goods)..... IV

Tools (plants engaged principally in making small or hand tools for working wood or metal)..... III

Tin plates (plants engaged principally in manufacturing same)..... III

The term "principally engaged in" means 75 per cent of the product mentioned. In other words a concern must devote at least 75 per cent of its resources to the manufacture of the product specified to secure preference.

This list, compiled by the Priorities Division of the War Industries Board, in co-operation with the Railroad Adminis-

tration, U. S. Shipping Board, War Trade Board, Food Administration, Fuel Administration, War Department, Navy Department, Allied Purchasing Commission and War Labor Policies Board, supersedes all previous lists. It was created by weighing the:

- (a) Intrinsic importance of the product during the war.
- (b) The need for maintaining or stimulating the production.
- (c) The proportion of the industry or plant devoted to war work.

Requirements of the industries named will have precedence over those industries not included in the list. There will be no complete or absolute preference between the four classes, the division being chiefly for the purpose of presenting a composite picture of the relative importance of each industry or plant embraced in each group. It is not intended that the requirements for example of class II will be fully satisfied before the needs of class III or class IV are met.

After the list of individual plants is made public each plant will be expected to file a report not later than the 15th of each month with the secretary of the Priorities Division, covering its activities during the preceding month. Failure to submit this report will cause such plant to be dropped from the preference list.

**War Contracts Delayed by Lack of Facts**

DETROIT, Sept. 10—The awarding of government contracts to concerns in this city and Michigan are being withheld because of negligence of some factory heads in returning the information requested in the questionnaire issued by the state division of the Resources and Conversion section of the War Industries Board.

At the present time the government is attempting to place contracts for large stamping operations and wood-working, but the Board of Commerce headquarters of the national board has not available sufficient details on the only plants which are in position to handle the contracts, and until such additional information is furnished no recommendations will be made to the government.

The great bulk of manufacturers have already filed the information desired, but a few large concerns and numerous smaller ones have not complied in filling out the questionnaires. Further steps in organizing the separate industries to facilitate plant surveys will be taken within a short time. Already the machineshop, stamping, forging and casting industries are organized.

**Ohio State Highways Transport Body**

COLUMBUS, Sept. 10—Organization of the highways transportation situation in Ohio is to be put on a solid basis under the direction of the National Council of Defense. A complete state-wide organization is to be effected for carrying out the work which is being undertaken by the highways transportation committee of the Council of National Defense. The personnel of the new organization in Ohio has not yet been determined upon. There is to be a state highway transport committee of five members. There will also be a state chairman appointed with the approval of the Governor. The state will be divided into five districts, each of which will be under the jurisdiction of one of the five committeemen. These central committeemen will have under them local organizations to be known as district highway transport committees, with a chairman for each county. Headquarters will be at Columbus, and the committee in gen-

eral will work under instructions from Washington. In each large center of the state it is intended to establish return load bureaus.

**Road Builders to Convene in Alpena**

ALPENA, MICH., Sept. 9—Arrangements are being completed by the Michigan State Highway Department and its representatives for the holding of the State Highway Department and Commissioners Road Convention in this city on Sept. 16 and 17. It is expected that the members of the county commissioners and most of the highway commissioners of the townships of thirteen counties will be in attendance.

**Women Workers in Demand**

WASHINGTON, Sept. 7—Increasing demands for women workers is reported from every section of the country. It is stated in one report that it is almost impossible to find women for non-war industries which pay wages lower than those offered by the war industries. The rubber factories in Akron and throughout Ohio are calling for and using considerable numbers of women, creating a shortage in other local industries in that state, according to a report. Growing demands for women for machine shops, munitions and light foundry work are reported. In the South there is a pronounced increased use of women for automobile tire repairing, elevator operating, etc.

**Government to Buy Platinum**

WASHINGTON, Sept. 9—In order to secure sufficient platinum to meet the war needs, the Government has decided to go into the market and purchase jewelry or scraps of the precious metal at the rate of \$105 per ounce. Citizens are asked to send their platinum to Raymond T. Baker, director of the mint. Platinum is used in great quantities for munitions manufacture, and the Government will regard the sale of private jewelry by individuals as a highly patriotic act.

**A Government Employment Service Bureau for Women**

DETROIT, Sept. 10—Four separate employment agencies for female labor have been amalgamated by the formation of the United States Government Employment Service for Women in this city, which has taken control of these bureaus. They are the Collegiate Bureau of Occupations, the Y. W. C. A. Employment Bureau, the Women's Division of the Employers' Association and the National League for Woman's Service. This bureau, which is under the direction of Miss Theresa Haley, aims to unite, coordinate and equalize women labor, and is conducted under the management of the Woman's Division of the Labor Bureau of the United States Government. There are bureaus in all the large cities of the country, with branches in the smaller surrounding towns and cities. It is the aim of these branches to adjust the supply of labor to the demand for it by directing women in localities where labor is plentiful to localities where there is a scarcity.

The bureau is divided into five branches—The Domestic Service Section, the Business Section, the Day Workers' Section, the Especially Trained Workers' Section, and the Factory Labor Section. The Detroit Branch already has branches in Saginaw, Traverse City, Grand Rapids, and Port Huron.

The bureau makes it a point to keep in touch with the civil service needs of the government. Every time an examination is announced civil service notices are also sent to the bureau, which not only inform applicants about these examinations but it advises and suggests as to which examinations are most suitable for the applicant, considering her education and training.

The Women's Division will not be confined to the war industries alone, however, as there is a big demand for woman labor in weaving, clothing and other trades.

ROCKFORD, ILL., Sept. 6—The Bergie National Spark Plug Co. has opened a Pacific Coast branch office in the Monadnock Building, San Francisco. H. G. Smith has been appointed manager.

# Calendar

**ENGINEERING**

Nov. 14-15—New York. Society of Naval Architects and Marine Engineers. Twenty-sixth general meeting. Engineering Societies Bldg., 29 West 39th Street.

**ASSOCIATIONS**

Sept. 19-21—Syracuse, N. Y. Semi-annual meeting of the American Gear Manufacturers' Association.  
Oct. 7-12—Milwaukee. American Foundrymen's Assn. and 5 allied organizations. Milwaukee Auditorium.

**SHOWS**

Sept. 8-20—Greely, Weld Co., Colo. Tractor Show, Central Community Fair.

Sept. 9-14—Milwaukee. Milwaukee Automobile Dealers, Inc. Fourth Annual Wisconsin State Fair. Hart J. Ruddle, Mgr.

Sept. 9-14—Syracuse, N. Y. Tractor demonstration (State Fair). J. Dan Ackerman, Secy.

Sept. 9-15—Madison, Wis. Tractor demonstration (State Fair). O. E. Remy, State Fair Secretary.

Sept. 12-13—Marion, O. Tractor demonstrations, Farm Bureau Associations. M. C. Thomas, County Agricultural Agent.

Sept. 14-21—Chicago. Automotive and Accessories War Exposition. Municipal Pier.

Sept. 19-21—Harrisburg, Pa. Tractor demonstrations, State Fair.

Oct. 1-5—Washington, Ga. (Wilkes Co.) Tractor demonstrations, State Fair.

Oct. 12-19—Atlanta. Tractor demonstrations Eastern State Fair and Automotive Exhibition.

Oct. 14-27—Dallas, Tex., Seventh Annual Texas Automobile Show. Texas State Fair.

Sept. 17-20—Riverhead, L. I. Tractor demonstration (County Fair). Harry Lee, Secy.

Sept. 30-Oct. 4—Trenton, N. J. Tractor demonstration (Trenton Fair). Harry B. Salter, Supt.

Oct. 16-18—Ottawa, Ont., International Plowing Match, Tractor and Farm Machinery Demonstration. Experimental Farm.

Oct. 30-Nov. 4—Shreveport, La. Tractor demonstration. State Fair.

Nov. 11-16—Phoenix, Ariz. Tractor demonstration, State Fair.

## The AUTOMOBILE

Vol. XXXIX  
No. 12

PUBLISHED WEEKLY AT 239 WEST 39th STREET  
NEW YORK, SEPTEMBER 19, 1918

Fifteen cents a copy  
Three dollars a year

*"The whole car is of the same high quality as its Red Seal Continental Motor."*

America's Standard  
Passenger Motor.  
Look for the Red  
Seal Nameplate

America's Standard  
Truck Motor.  
Look for the Red  
Seal Nameplate

The manufacturer who uses the Continental Red Seal Motor in the car or truck he makes is a manufacturer whose standards are high.

He uses the Continental because he knows it is a car motor he can depend on—a motor embodying nothing untried, nothing experimental—a motor whose worth is a certainty.

Naturally, he exercises the same good judgment in the selection of the other units that go to make up his car or truck. Reliability is his watchword, and he sees to it that everything in his product measures up to the high standard set by the Continental Red Seal Motor.

To-day over 160 such manufacturers use this famous motor in the cars or trucks they make. It is significant that among these are found many of the leaders in the motor vehicle industry. It is equally significant that the dealer in Continental equipped vehicles is usually a very successful one.

Look for the Red Seal (shown above) on the motor in the car or truck you buy. It's your guarantee of motor quality—as well as your assurance of a good car or truck.

STANDARD POWER FOR AUTOMOBILES AND TRUCKS

## From Passenger Cars to Master Trucks —That Sounds Reasonable

**W**AR requirements—the increasing need for motors in essential industries—the Nation's transportation problem—mean a steady and increasing demand for Motor Trucks.

You, like other far-sighted business men, are undoubtedly thinking of adding a line of Trucks. Not merely as a side issue or a fill-in, but as a basis for all time to come.

Choose the right Truck—the right maker. Don't take chances. This is the time to be sure of your connection. The established, reliable maker alone is certain of what he can do—and what he can offer you.

Choose a Truck that has time tried service built into it—a Truck requiring the minimum time of your service man. In the present activity and scarcity of labor, this should mean much to you.

The agency for Master Trucks in your

locality is your very best start in the Truck business.

We have a big story to tell you—a story in a language you understand—**Specifications.**

A story of sixteen years of successful Truck engineering and Truck building experience.

Of real sales and advertising co-operation—a story of the Master's true leadership in its field.

This is a story you should know—regardless of your present plans. It is full of selling interest—of real opportunity.

We have a limited number of good territories still open. Your automobile selling experience is valuable to you and to us.

May we place this story before you—by mail—with our liberal dealer proposition?

As salesman to salesman we would appreciate the courtesy of an interview by mail.

*Full Line—Six Sizes, from 1½ to 6-Ton*

**MASTER TRUCKS, Inc., 3132-3138 S. Wabash Ave., Chicago**

*Until the War is won, Master Trucks will be sold for service only in essential industries as defined by the War Industries Board*

# MASTER TRUCKS

## Making War Maps by Camera

### AERIAL PHOTOGRAPHY NOW AN IMPORTANT AID IN SUCCESSFUL MILITARY OPERATIONS

#### British Army Issues Official Instruction Book for the Interpretation of Airplane Photographs

**A**ERIAL photography, a new science, and probably the most important in military operations, is just advancing from infancy. A photograph taken from an airplane is an enigma to those not versed in this science. The British Government, following exhaustive studies and experiments, has issued to its army an official instruction book for the interpretation of airplane photographs. The first instruction book, now available for publication because the photographs are no longer true, is presented here almost in its entirety. It shows that so simple a detail as holding the photograph in the wrong position will completely confuse the observer. For example, a sunken road, with the photograph reversed, becomes an embankment because of the direction of the shadows, which are reversed with the photograph.

More intricate details include the understanding of the different shadows, the lighter and darker shades, the detection of camouflage, location of traps, discovery of lines of communication, ammunition dumps, dummy and genuine batteries, movements of troops, etc. The enemy, for example, frequently selects two or

three large shell holes in no man's land and establishes an outpost there, developing the shell holes into substantial fortifications and opening a line of communication by a narrow path between the shell holes and the front line trenches. An Allied airplane detects these shell holes

by a photograph. The infantry commander is notified. At night a detachment goes over the top and surrounds and surprises the enemy shell hole and outpost, usually returning with prisoners.

Photography from airplanes for reconnaissance purposes was first experimented with by the British service in France late in 1914. Before the war such experiments had not been successful, and aerial photography had been confined to the work of balloons and kites.

The airplane photography difficulties were chiefly from engine vibration. Shortly after the war, with the establishment of trench warfare, balloon and kite photography was found impracticable, and new experiments in airplane photography resulted successfully. The next difficulty was interpretation of the photograph. Oat, wheat and corn fields, barracks, solid

*The right and wrong way to examine a photograph. The photo shows an embankment of slag. Reversed, it has the appearance of an excavation. This is caused entirely by the shadows. Shadows falling away from one give the appearance of an excavation, and falling toward one the impression of a raised object*

NOTE.— The sign to be written clear of the object on the photo, with a detached arrow pointing to it (when necessary)

Conventional signs for use on airplane photographs. By the use of simple signs a photograph can be more quickly and easily marked to show the meaning without confusion

formations of troops, and similar objects, as reflected in airplane photographs, bear no resemblance to their ground appearance, and many experiments were necessary to establish the identity of the different objects reproduced in the photographs.

The accuracy of the photograph is indisputable. One plate can cover a square mile of territory, and the entire maze of detail can be taken in one one-thousandth of a second. It is even possible to take a photograph of a large number of railway trucks on trains at a railway junction from a height of 17,000 feet and secure the exact number of individual trucks from the picture.

Another advantage of the photograph lies in the fact that it reflects the scenes dispassionately, while the impressions of the human observer, who might be excited by working under trying conditions, might be exaggerated. Photographs taken periodically of the sector consist at the same time of a biography and a map. Small changes in the trench construction or in the topographical illustrations which the eye could not detect are immediately apparent.

The air photograph is the Sherlock Holmes for camouflage. It often registers the whole history of the construction of an emplacement, showing it prior to, during and following the construction of the camouflage, and marking it as a "tender spot" for artillery fire, following completion.

Two kinds of air photographs are taken, the vertical and the oblique, the former being the most useful for intelligence work and mapping. The oblique photographs are used for the detection of camouflage and to give a correct idea of the land, contours, etc. They are also

Topographical studies. In all three of these photographs the direction of light is from above. The top picture shows a road banked on one side. A stone quarry shown in the center view. Railway embankments show the existence of railroads, as clearly discernible in the bottom picture

more simple in interpretation, and are used by the experienced infantry and artillery commanders. Mosaic photographs are made by joining a number of vertical photographs at a given locality to make a complete photograph of a city or district. They are usually all taken at the same height and at the same time by a number of planes. In the same way, continuous-line photographs are made by joining strips of overlapped photographs

The map and photograph above show trenches under construction on the Droucourt-Queant line occupied by the Germans. Point No. 1 shows possible camouflage netting over a battery position. No. 2 indicates a light railway. No. 3 shows an air line route for telegraph or telephone wires from Rouvroy to Beaumont. No. 4 indicates a buried cable line. No. 6 shows gaps through the barbed-wire entanglements

A mosaic airplane photograph made up of 6 distinct photographs pieced together to make the complete city of Thionville, which was bombed by British aviators March 5, 1918. This allows the Intelligence Division of the British Army to make up an accurate map of the city. The accuracy with which this photograph is pieced is shown by the perfect meeting of streets and bridges over the river

*Shadow diagrams showing the effect of light and shade on trees, haystack, gun emplacement and organized shell hole as viewed from above*

important roads, railways, canals, etc. To secure these, an overlap of about three-sixteenths is worked out in the time intervals between the exposures based on the height and speed of the airplane. Stereograms are much used for detection of camouflage and contours. These are made by taking 2 photographs of the same point at varying intervals, according to the height and speed, and using them in a stereopticon apparatus. For instance, a machine traveling at 60 m.p.h., ground speed, at a height of 1200 ft. would take its second photograph about 2 seconds after the first.

Accurate trench maps are made from the aerial photographs and supplied to the infantry and artillery. In the British Eastern theater of war, where the army was in complete ignorance of the country, maps of the entire district have been made from aerial photographs.

*Trench construction and barbed-wire entanglements. This photograph was taken after the battle of Vimy Ridge, when the enemy was forced to the Oppy-Mericourt line. Barbed-wire entanglements which are shown in the photograph in the first line of trenches are penetrated by saps pushed through the wire for the commencement of the new line, No. 1, where another light protection of wire, No. 2, was erected prior to the digging of the trench. No. 3 shows gaps in the old wire across roads. These gaps have been repaired. No. 4 is another trench commenced in the rear of the position and which when completed will give the enemy four lines of trenches. No. 5 shows a tramway*

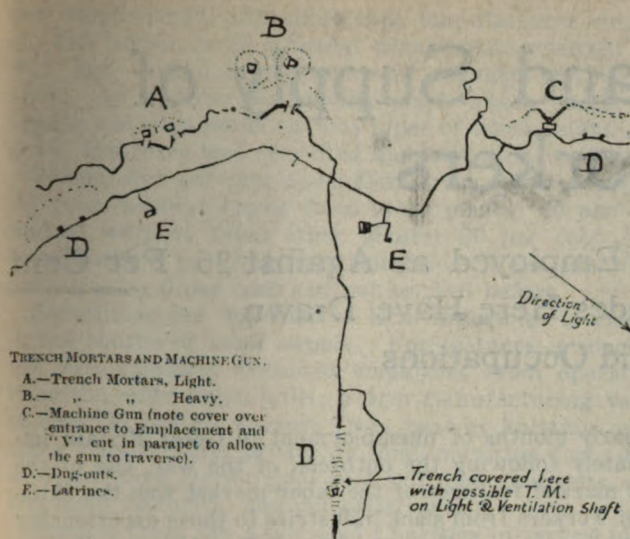

*Machine gun emplacements. This photograph shows a new type of machine gun behind the front trench line on the Oppy-Neuport line. The emplacements A are connected underground to the island traverses C. In the case of B, the machine gun nest communicates with the trench on the other side by an open sap. The machine guns fire from open emplacements over the heads of the infantry in these trenches*

The intelligence department of the army relies importantly on its aerial photographic section for its information. Through these pictures it detects the gaps and passages through barbed-wire nets, the amount of damage done to enemy wire entanglements, machine-gun emplacements and dugouts by artillery fire, and by means of wireless from airplanes directs the artillery fire until it attains perfect marksmanship.

Photograph and outline map drawn from it showing trench mortar and machine gun emplacements

An oblique photograph showing a point at which the Allies are now fighting—the Hindenburg line west of Bullecourt. In front of the front line trenches are barbed-wire entanglements which measure more than one-half mile in width. This particular point is exceptionally well protected, as it is an ammunition station and an important railway center. A sunken road paralleling the railroad is plainly discernible

# The Demand for and Supply of Women Workers\*

Only 8 Per Cent of American Women Now Employed as Against 26 Per Cent in England—So Far Metal Trades Here Have Drawn Chiefly from Poorer Paid Occupations

**D**URING the first year after the United States entered the war the general introduction of women into occupations previously filled by men was discouraged in many quarters. At the beginning of 1918 the United States Secretary of Labor was quoted as expressing the opinion that there was an ample supply of labor both for the army and for industry; that the problem was one of proper adjustment, and that it was the policy of the Labor Administration to prevent the introduction of women into new occupations as long as men were available.

This attitude was reflected in the position taken by many State councils of defense and other official bodies. Private associations interested in safeguarding labor standards were also extremely conservative toward the wider employment of women. At the end of 1917 reports issued by the New York State Industrial Commissioner and by the American Federation of Labor maintained that employment difficulties arose not from a real labor shortage but from defective distribution, due to increased activity in some industries receiving war contracts, and to greatly reduced business in industries not essential for the prosecution of the war. Many manufacturers were of the same opinion.

## Will Require Four Million Workers

To-day, however, the needs of industry are becoming more urgent. The United States Employment Service recently estimated that from 3,000,000 to 4,000,000 workers will be required in essential occupations, including agriculture, during the next twelve months. It is reasonably certain, therefore, that there must be a far-reaching occupational readjustment, which will compel the admission of more and more women workers to industry.

In the United States, the proportion of the female population now employed is approximately 8 per cent, as against 26 per cent in England. To make the number of women employed in the two countries proportionate would mean the addition of 8,152,135 women to the ranks of industry in the United States. While such a radical readjustment as was effected in England may never be necessary, preparations for the gradual introduction of women into industry can be most satisfactorily made now, while the proportion of skilled men is still so high that changes should not seriously interfere with production of materials required for war purposes.

In the discussion of women's employment in occupations new to them it has often been assumed that they came from a class not previously employed. That this would be highly improbable, at least, might be inferred from the experience of other belligerent countries. After

the early months of unemployment in Great Britain immediately following the outbreak of the war, one of the most marked features of the labor market was the shifting of workers from slack industries to those experiencing unusual activity. For example, it is estimated that in Great Britain 400,000 women were drawn from the domestic servant class and from small dressmaking establishments into the war industries, which offered higher wages. Of 1,407 female workers in a French munition factory, in 1915, all but 480 had been previously employed in some wage-earning occupation.

In Canada, where the labor situation is much more comparable to that in the United States, such a shifting from the so-called "women's industries" was also characteristic. The Deputy Minister of Labor for Canada reported that "the movement of woman labor was chiefly from the poorer paid to the better paid industries."

Many employers interrogated in this investigation likewise secured their women workers from other factories, though not necessarily from the same occupations. One manufacturer of elevating and conveying machinery, employing nearly a hundred women, stated that 50 per cent of them were previously doing machine work. An automobile manufacturer who utilizes women chiefly on sewing machines in the trim department, obtained them largely from those doing similar work in other factories. The majority of the winders in a plant manufacturing ignition apparatus had been similarly employed elsewhere. In one establishment, women who are molding and making, carrying and packing cores are largely Belgians who were accustomed to doing heavy manual work in their own country.

## Transferred Between Departments

Some employers did not even go outside their own plants to secure women for new work, but simply transferred them from one department to another. In some establishments, women previously employed as inspectors or assemblers were transferred to machine work. An employer who intends to introduce women on a large scale within a few months reported that he should give the preference to friends and relatives of his employees. This plan has already been successfully tried in several establishments.

In other cases, such transfers were carried out among the male employees so as to avoid introducing women on shop work. For instance, one employer reported it to be his policy to transfer men from clerical to mechanical positions when that could be done, filling the office vacancies thus created with women. He stated that training had developed many inferior clerks into good mechanics.

Frequently, women who have entered the metal trades in the present war-labor emergency came from a great range of occupations not immediately related to their

\*From the Report on Wartime Employment of Women in Metal Trades of the National Industrial Conference.

new employment. An automobile manufacturer employing 423 women in 23 different departments reported that they had seldom been previously engaged on machine work. In another automobile plant where nearly 300 women are engaged in various types of machine and shop work, the force was recruited approximately as follows:

Twenty-five per cent assemblers from other plants; 20 per cent machine hands from other plants; 20 per cent clerical workers from other plants; 20 per cent from housework; 5 per cent from laundries; 5 per cent from restaurants; 5 per cent had not worked before.

Sometimes the influence of local industries is evident in the source of labor supply. For instance, a machine tool establishment obtained employees from operatives in cotton and woolen mills; a firm manufacturing valves secured its female workers from near-by knitting mills; and a manufacturer producing small munition parts drew on department stores, cloak and suit manufacturers, electric lamp factories, and domestic service.

Reports from the Associated Charities in several cities indicate a decided increase in the employment of negro women in many kinds of manufacturing establishments; as yet, this class of female labor has not been extensively utilized in the metal trades and similar industries. In a recently published article the representative of a company manufacturing steamfitters' supplies recommended negro women for the operation of light semi-automatic machines, punch presses and drill presses, at the same time suggesting that least friction will result if they are employed in departments separate from the white workers.

Higher wages were an important factor influencing the shifting of female labor. Thus women formerly in domestic service constitute a considerable proportion of new workers in the metal trades; the shorter hours and other working conditions may have been an added consideration. To some extent this also explains the movement of women from other industries into the metal trades. At the end of 1917 a leading textile journal contained a warning to manufacturers in the cotton and woolen industries that they must improve the surroundings and working conditions in their factories in order to meet the competition of war industries for woman labor, and reduce their turnover.

In 85 establishments reporting for the present investigation, 17.3 per cent of a total of 22,750 women employees were married. Many men who have entered the national service were the only wage earners in their families, and very frequently wives who were employed before their marriage have found themselves obliged to return to work. Employment of an increasing proportion of married women in industry has, however, been one of the striking social changes of the past thirty years.

In England the first instalments of war workers, especially those trained in technical schools, were secured through regular employment channels, through advertising, and through canvassing friends and relatives of those already employed, but the British Government has since drawn on a more educated type. Whether it will be necessary to recruit workers from this source in the United States will obviously depend on the duration and future demands of the war.

# Unmined Petroleum Supply Limited

Seventy Barrels Per Person in United States—Vast Areas of Oil Shales in Reserve  
—Greater Extraction of Values Necessary—Much  
Production Wasted

By Allen Sinsheimer

**W**ASHINGTON, Sept. 17—The unmined supply of petroleum, now available, in the United States is 70 barrels per capita. The presence of extensive deposits of oil shale in this country, however, removes the danger of early physical exhaustion of oil but cannot be considered license for continuation of the present wasteful customs of production and use. There are 7,000,000,000 barrels of petroleum still under ground in the United States, as compared with approximately 3,500,000,000 barrels which have been produced. One-half of the petroleum produced yearly is wrongly used for steam raising. The petroleum consumed in and exported from this country this year exceeds the production in the United States and that imported from Mexico. The cracking process, because of the great demand for gasoline and decreasing supply of petroleum, may be regarded as the hope for the future. Up to this time gasoline has been the main prop to the cost structure of petroleum refining, but the entrance of the United States into the war, with the consequent increased demand for fuel oil, has changed the complexion of the oil situation. And as crude petroleum production has been unable to keep pace with the consumption of fuel oil, serious shortage results even while gasoline is ample for all needs. The automobile

has been the prime factor in developing gasoline production.

These statements, taken from a bulletin issued by the United States National Museum following a comprehensive survey of the petroleum situation by Chester G. Gilbert and Joseph E. Pogue of the Division of Mineral Technology, form the most important details of the report.

The bulletin, which is exceedingly timely, has been prepared to interpret the significant aspects of the petroleum situation, in non-technical language. Following a discussion of the nature, occurrence, origin, distribution, production, transportation and refining, the report takes up the important question of limitation.

## The Extent of the Supply

The proven and prospective oil fields of this country, it says, are broadly known and the petroleum reserves may be estimated within a reasonable margin of error. The accompanying chart, reproduced herewith, shows a production of 350,000,000 barrels in 1917 and a probable production of 575,000,000 barrels in 1930. This chart, it is said, shows that a big fraction of domestic petroleum is gone; whether that fraction is one-third as present knowledge indicates makes no difference in

the consideration demanded by the situation and we face an economic fact that must be reckoned with now.

"It is, of course, very evident," adds the statement, "that the present tendency cannot persist to the point of even approximate exhaustion, because conditions such as price increase, growing imports and others, naturally arising, will serve to relieve the tension and thus spread the remaining supply over a greater number of years. So in spite of its sensational character, the physical exhaustion of the petroleum resource is a theoretical matter of purely academic interest. But of practical importance is the period of economic stress that is ushered in when the resource faces a greater demand than it can fill in the customary manner. That is a period of readjustment to meet the new conditions and arrives far in advance of physical exhaustion."

#### Constant Local Adjustment

Local adjustments are constantly under way even now, says the statement, as petroleum fields reach their production climax and decline, and these fields forecast the history of the resource in its entirety. This can be plainly seen in Fig. 2, shown herewith. Since petroleum resources are not only limited in size but also in ability to sustain the present rate of increase in production, the bulletin continues, and since trucks, tractors, airplanes and passenger cars forecast a still greater demand for gasoline it is probable that this will be one of the important continued products of petroleum and that it must develop intensive production.

The use of fuel oil for steam raising is regarded as a waste, unavoidable at present because of existing facilities necessary and demanding it, but is a practice which must be discontinued in the near future. Over half of the petroleum currently produced is used as fuel for steam raising. Kerosene consumption, although increasing, must be discontinued to meet the lighting demands of rural districts. Lubricating oils can be manufactured from oils distilled from shale and from coal as is now done in those countries lean in petroleum, such as Scotland and Germany. At the present time in this country petroleum is produced and manufactured into products far in advance of lubricating needs, which means that the lubricating portion of the resource is being exhausted at a rate dictated by the demand for oil for power generation. Thus the exhaustion of our principal lubricant resource is being accomplished with much greater dispatch than is justified by true necessity since part of the fuel demand could be filled by means such as coal and hydroelectricity not involving a sacrifice of potential lubricants.

#### Conserving the Supply

The outbreak of the European war in 1914 found the United States petroleum industry suffering from low prices caused by gross overproduction resulting from large yields in Oklahoma. These yields declined in 1915 and this, combined with the general increase in automobile consumption of petroleum products, increased the price. The entrance of the United States into the war with the consequent growing importance of petroleum products as war needs further increased the prices and demand, and the United States is now consuming and exporting more petroleum than she is producing from her own wells and receiving from Mexico. The discrepancy which is growing monthly is covered by a draft upon the petroleum storage in this country, which amounted to 153,000,000 barrels Jan. 1, 1918. This storage cannot be safely reduced below 50,000,000 barrels, which are needed to fill the pipelines and keep the whole industry in operation. Fig.

Fig. 1—Chart showing the present tendency of the United States in respect to its unmined reserve of petroleum

3 shows the current petroleum situation. Transportation from Mexico to this country is in such condition that there is scant hope of increasing the supply from that source unless concrete tankers can be quickly constructed.

Discussing the problem itself, the bulletin points out that the enlargement of the resource capacity can be brought about in three ways:

1. By prolonging the life of the unused portion of the domestic resource as it is now known.
2. By developing low grade domestic sources not yet drawn upon.
3. By building up the use of substitutes particularly for gasoline for which there is a heavy growing demand.

#### Production Waste Must Be Eliminated

Prolonging the life of the petroleum reserves can be accomplished by discovery of new oil fields, elimination of wastes in production, greater extraction of values and development of foreign supply sources. There is not much hope for new fields in this country. The petroleum resources are now fairly accurately measured and there is no basis for believing that great areas of oil reserves lie undiscovered. Much can be accomplished by the elimination of production wastes. Present practices allow from 30 per cent to 90 per cent of the oil to remain under ground. An appreciable percentage of that produced is lost by fire and much is dissipated by seeping and evaporation due to inadequate storage facilities. On the average, therefore, it is said, less than 25 per cent of petroleum under ground reaches the pipe line. Subtracting the losses involved in improper and wasteful utilization the recovery factor becomes as low as 10 per cent. Waste connected with oil well drilling is caused by the harmful infiltration of water from water bearing strata and the uncontrolled escape of natural gas encountered in the course of drilling. Frequently there are wastes caused by unexpected gushers when the oil runs rampant over the ground. This often results in fires.

Greater extraction of values, it is recommended, can be accomplished by the extension and further improvement of the cracking methods of distillation which were discussed at length in last week's issue of AUTOMOTIVE INDUSTRIES, through the improvements in the design and efficiency of the internal-combustion engine, through the widening use of the Diesel type of engine,

through gradual deflecting fuel oil from its rôle of a steam-raising understudy to coal, and through a carefully planned program for building up a great oil by-products industry to give multiplications of value to the portion of oil left after energy, light and lubricating values are extracted. The by-product substances manufactured from crude petroleum afford great possibilities for future industrial usage for edibles, synthetic rubber, dyestuffs, etc. The Diesel type of engine, it is said, is the most economical heat-engine, from a thermal standpoint, that has been devised and most nearly approaches theoretical maximum efficiency.

#### Mexican Fields and Our Shale Deposits

Since 1911 this country has been drawing upon the Mexican oil fields at an increasing rate, Mexico supplying 10 per cent of our needs in 1917. The Mexican pools are the richest in the world and are capable of much greater annual production than has yet been taken from them. The Central American region has promising oil districts but none have developed in any way comparable to the Mexican deposits. The Mexican deposits, recommends the bulletin, should not be so wastefully exploited as have been those of the United States.

Within the last 5 years geological explorations have established the existence of vast areas of black shale in Utah, Colorado and Wyoming which are capable of yielding, upon distillation, around 50 gallons of oil, 3000 cu. ft. of gas and 17 lb. of ammonium sulphate. Oil

shale is not supposed to contain petroleum, but applications of heat have caused reactions forming oil resembling petroleum from which, it is thought, products similar to those yielded by petroleum can be obtained. There have also been other oil shale districts found in Nevada, California, Montana, Arizona, Oregon and several other states which, although not so large, give promise of an immense area in the aggregate and represent a potential oil source sufficient to supply this country for hundreds of years.

Because petroleum is not fixed in position and much of the production is won through the efforts of small operators to reach oil quickly there is a ruthless sacrifice and this is one fundamental cause of waste. The gambling character of wildcat drilling leading to a desire for quick returns with little regard for engineering efficiency is another. These must be prohibited. A general constructive economic policy leading to sound development of petroleum industries, discouraging unrestricted competition in production is necessary. Encouragement of the by-product, oil shale development, benzol and alcohol production and the use of more efficient internal combustion engines form the important solutions. The exploration for petroleum as now guided by the principal of gambling, the competitive extraction of petroleum within single reservoirs, the utilization of petroleum in part by the principle of perversion as its usage for steam raising, must all be banned, summarizes the bulletin, if we are to place petroleum resources on a sound basis.

## Longitudinal and Cross Section of American Sleeve Valve Engine

*This is the latest improved design of this engine, which differs in various details from the engine exhibited at the New York show last winter*

# Tests of a Sleeve Valve Engine

Engine of the American Sleeve Valve Motor Corp. Has a Single Sleeve Rot at Uniform Speed—Manograph Diagram and Horsepower and Torque Curves Show Its Characteristics

A REPRESENTATIVE of AUTOMOTIVE INDUSTRIES recently had occasion to visit the laboratory of the American Sleeve Valve Motor Co., 1926 Broadway, New York, where development work is at present being done on the American sleeve valve engine. This engine was exhibited at the New York show last winter, and a brief description of it appeared in these columns at the time.

It will be remembered that there is a single sleeve in each cylinder between the cylinder wall and the piston which rotates at uniform speed making one revolution to four of the engine crankshaft. This sleeve has two equal-sized ports cut into it, one directly opposite the other, which ports are adapted to register with ports in the cylinder wall and

in the extension of the cylinder head down into the thereby performing the inlet and exhaust functions.

The cylinders are of 4 in. bore and 5 in. stroke, piston displacement for the four cylinders of 251.2. These dimensions it will be well to remember in connection with the test results to be given further on. All four cylinders are cast in a block, and there is no water space between each pair of outer cylinders. The revolving sleeves are driven through helical gears at their lower ends, meshing with corresponding helical pinions on a longitudinal shaft. The latter is driven from the crankshaft through a pair of helical spur gears without change in rotative speed. There are only two helical pinions on the longitudinal shaft

Set-up for dynamometer and manograph tests

*Close-up view of the engine, manograph and arc lamp*

mesh with bronze helical gears on two of the revolving sleeves. The other two sleeves are driven by helical gears formed integral with them meshing with the two bronze helical gears. The cast iron helical gears are cut in with teeth of the opposite hand from those of the bronze gears in order to permit of the proper mesh. The entire reduction of 4:1 is effected between the helical pinions and gears, the gear train at the front of the engine consisting of equal-sized driving and driven gears and a somewhat larger intermediate gear.

Little need be said of the construction of such parts as crankcase, crankshaft, connecting rods and pistons, as they do not differ materially from conventional designs. The crankcase is divided horizontally through the crankshaft axis and all three crankshaft bearings are carried by the upper half. The crankshaft is partly balanced by extending the crank arms adjacent to the main bearings an equal distance past the main journal in both directions, and undoubtedly a very rigid crank is produced without incurring the disadvantage of excessive weight by making the central arms unusually thick and boring them out.

#### Separate Head for Each Cylinder

The water jacket extends practically the entire length of the cylinder, and the cylinder block rests on the crankcase by a flange on the water jacket wall rather than the cylinder wall, as the space below the cylinder wall is taken up by the sleeve gear. It is interesting to note that the bronze gears are doweled into the sleeve by means of integral dowels formed with the aid of the oxy-acetylene torch.

A rather interesting form of cylinder head is used, which is separate for each cylinder. It consists of an aluminum casting over which is screwed a steel sleeve. Two longitudinal slots are cut in the latter, quite close together and extending nearly the entire length of the sleeve, one from one end and one from the other. This gives the threaded sleeve a certain flexibility, making it similar to a piston ring. At the upper end of the sleeve the thread is omitted and this end passes over a couple of expansion rings in a single groove in the piston head, which rings exert a pressure against the steel sleeve tending to expand it against the revolving sleeve.

Ports of rectangular shape are accurately cut in the steel sleeve, these being somewhat smaller than the ports cast in the cylinder head and thus determining the exact moments

of the beginning and end of the valve functions. The ports in the revolving sleeve are larger or wider than those in the cylinder wall and cylinder head, with the result that these latter are fully uncovered for a certain period of time. Owing to the fact that the valve sleeve rotates at uniform speed, the valve opening increases rapidly and uniformly from nothing to the maximum, then remains for a while at the maximum and then decreases to zero in the same way as it increased to maximum.

Two important problems connected with the design of an engine of this type are the lubrication of the sleeves and the prevention of leakage of gas from the ports around the valves. These two problems are somewhat connected, for with proper lubrication of the sleeves around the ports there is no danger of gas leakage. It will be seen that the revolving sleeve is cut with helical oil grooves over its whole length below

the ports, which are designed to distribute the oil. But oil from the spray can get on to the revolving sleeve only at the lower end, and it would have a long distance to travel to reach the extreme upper end, hence a special oil head is connected to each cylinder near its top.

The engine is of remarkably smooth exterior, as there are no valve pockets and valve spring housings, the inlet manifold is cast integral, the exhaust manifold bolted directly to the cylinder block and the spark plugs submerged below the top of the cylinder heads. The plugs are evidently not

Gibson, who introduced the in this country, has been acting in the American Sleeve Valve Motor rough study of the engine by means of the diagrams taken by him are to insure absolute accuracy in deter- own on the diagrams, the diaphragms calibrated by means of a Schaeffer r. This consists of a small cylinder on which rests a piston supporting a e bore of the cylinder is accurately r square inch on the oil can be readily be made anything desired by merely n the piston or plunger. By admitting agm chamber of the manograph and ob- of the spot of light corresponding to

different weights on the plunger of the gage tester, data may be obtained for a calibration chart of different diaphragms. Diaphragms of different gages of metal are used for different tests. For instance, when it is desired to obtain only the compression curve of the engine a diaphragm of lighter gage is used than if the explosion curve is to be traced, and if the exhaust and intake curves are to be obtained only, use is made of a diaphragm of very light material and a "pillow" of metal is placed behind it which limits the amount of its deflection.

Two of the photographs reproduced herewith show the set-up for these tests.

The engine is connected to a Herschell-Spillman hydraulic dynamometer. Fuel is drawn from a tank on a weighing scale supported on a shelf high up on the wall so that gravity feed may be used. The manograph is supported directly above the engine on a frame suspended from the ceiling. It is a single diaphragm instrument, and connection to the different cylinders can be readily made by means of valves. In the view of the complete engine and dynamometer may be clearly seen both the pressure connection and the motion connection to the manograph. Motion is obtained

Without exhaust pipe—Diagrams taken with pillow behind diaphragm—With long exhaust pipe

600 r.p.m.—Full throttle diagrams—1800 r.p.m.

from the end of the valve shaft, which runs at the same speed as the crankshaft and is more accessible than the latter.

Adjacent to the manograph will be seen the electric arc lamp which furnishes, through a pinhole, the spot of light that traces the diagram. Ordinarily the spot of light traces the curve on the mat glass surface of the manograph, the entire diagram standing out clearly, owing to the persistency of vision. But a film pack is attached to the instrument, and a photographic record of the diagram can be obtained with very little trouble.

A number of diagrams obtained from the American sleeve valve engines are reproduced herewith. The first two were taken with a diaphragm only 0.0075 in. thick with a pillow block behind it. This will indicate pressures only up to about 12 lb. per sq. in., as at higher pressures the diaphragm rests against the pillow block. Therefore, the variation of pressure during the exhaust and intake strokes only is recorded. The uppermost, horizontal line is traced during the explosion stroke, the diaphragm lying snug against the pillow block. At the end of the power stroke the pressure drops and comes within the range of the diaphragm. During the return or exhaust stroke the spot of light accurately indicates the variation of pressure in the cylinder. It will be observed that the only noticeable difference between the two diagrams taken with the light diaphragm and pillow block is that one shows a notable increase in pressure at the end of the exhaust stroke while the other does not. What caused this difference was that in the first case the engine exhausted through a long exhaust pipe extending clear across the room, while in the other case it exhausted directly into the atmosphere. In the first case, owing to the overlapping of the exhaust strokes of succeeding cylinders, some of the spent gases from a cylinder just beginning to exhaust are blown back into the cylinder completing its exhaust stroke. The rise in pressure amounts to about 3.5 lb. per sq. in.

Two power diagrams are also shown, of which one was taken at 600 r.p.m. and the other at 1800 r.p.m. The conditions are otherwise substantially the same. It will be noticed that the low-speed diagram is absolutely smooth, while the high-speed diagram shows a wavy formation just before and after the point of ignition. The statement was made by a speaker at an S. A. E. meeting some time ago that the flicker of the manograph light near the point of ignition, which had always been supposed to be due to inertia of the moving parts, was in reality due to complicated chemical

*Exhaust side of American sleeve valve engine*

actions during the combustion within the cylinder. This was quite interesting, but it would have been still more interesting if proof had been put forth to substantiate it. If the combustion involved several successive chemical reactions, involving heat liberation at different rates, we would probably have the wavy line also when the engine runs at low speed.

Another point brought out by a comparison of these two diagrams is that at high speed the engine does not get rid of the spent gases nearly as promptly as at low speed. A thing that is more difficult to explain is the more nearly straight compression line in the high-speed diagram.

A horsepower diaphragm of the engine is included in the illustrations. This shows an output of 26 hp. at 1000 r.p.m., corresponding to a brake mean effective pressure of 82 lb. per sq. in., and 50 hp. at 2100 r.p.m., corresponding to a b.m.e.p. of 76 lb. per sq. in. Ignition during these tests was by a Bosch magneto, and the carbureter used was a Zenith.

The engine complete weighs 581 lb. That it is of rugged construction may be seen from the photographs and drawings.

# The Theoretical Indicator Diagram

## A Method of Predetermining the Gas Temperatures and Pressures for Various Points in the Engine Cycles from the Chemical Composition of the Charge and the Physical Properties of the Components

By O. A. Malychévitch, E. S. A., C. M.

**T**HERE has always been an important discrepancy between the temperature and the pressure of the exploding gas in an engine cylinder as obtained by actual measurement and the values arrived at by calculation based on the heat content of the fuel in the charge and the specific heat of its components. In fact, while the theoretical combustion temperature is often given as more than 4000 deg. Fahr., the actual combustion temperature is only about 3000 deg. Fahr. If the theory was complete and took account of every factor affecting the temperature of combustion it should give results comparable with those obtained by measurement. The author of this article endeavors to evolve a theory of combustion that takes into account all of the influences that lower the combustion temperature and to give results in accordance with practical observations.—EDITOR.

**E**NGINES of airplanes, and especially those of racing cars, serve as models on which new improvements are first tried out. If they prove themselves, the improvements are later on embodied in other types. On the other hand, defects in design are also repeated. Nevertheless, rapid progress has been made in the development of high-speed engines for motor cars and airplanes.

The race for the Grand Prix in France in 1906 was won by a Renault car with an engine of 165 mm. bore and 150 mm. stroke, having a piston displacement of 12,850 cc. (785 cu. in.). This engine developed 100 hp. at a maximum car speed of 135 kilometers per hour (84 m.p.h.). In the race of 1914 the Peugeot engine of 92 mm. bore and 169.5 mm. stroke, having a piston displacement of 4500 cc. (275 cu. in.), developed 110 hp. at a car speed of 170 kilometers per hour (106 m.p.h.). It will be observed that, notwithstanding the great decrease in the piston displacement (65 per cent) the Peugeot engine developed greater power and much higher speed than the Renault of 1906.

The increase in the power of the engine is by no means the only progress made during a period of about eight years. All modern cars equipped with high-speed engines are much lighter in weight, run on lighter tires and consume less fuel and lubricating oil.

Admitting that an improvement in the form of the combustion chamber is obtained by placing the valves in the head of the cylinder, that modern carbureters are very efficient, that the quality of steel used enables high stresses to be borne, and that the details of the engine are considerably improved, one marvels that such a great difference should still be possible between the two above-mentioned types of engine. The reason for this difference is not to be found in improvements of separate parts, nor in better performance of the carbureter, but

in the rapid increase in the number of revolutions (i.e., in the linear speed of the piston), and in successful efforts to solve the problems pertaining to the thermodynamical process of motor-car engines. To these two factors is principally due the above-mentioned progress, which enables an engine with decreased piston displacement, and consequently lighter, to produce much greater power.

On the other hand, practical conditions force manufacturers to adopt standard types of engines, and the annual reports of motor car exhibitions show a tendency to limit the number of types of engines and cars, coupled with endeavors to make the types more efficient, more comfortable and economical. The problem of "economical transportation" directs the efforts of engineers to the question of designing a heavy oil-burning engine (Hvid, Scott-Junkers type) for agricultural tractors, trucks and even motor cars and airplanes, and some method must be adopted for developing the best type of engine from the standpoints of durability, flexibility and other desirable qualities.

A method which may be recommended is that of the experimental investigation of thermodynamic processes in the laboratory as well as in the factory, for different kinds of engines. The data obtained, arranged by such an authoritative body as the S. A. E., could be passed to the drawing rooms of the factories, to serve as a basis in the design of engines. Such data as volumetric efficiency, suction, explosion and exhaust temperatures and pressures of engines using different compression ratios, running at different speeds, etc., will serve in laying out the theoretical indicator diagrams. The latter, when compared with the real indicator diagrams of the completed engines, will serve as a check on the calculated temperatures, pressures, heat losses, coefficients, etc.

From a series of indicator diagrams taken from different types of engines, a mean indicator diagram may be constructed which will permit of a more accurate determination of necessary data, including the values of  $n$ ,  $n_c$ ,  $T$  (equation 40 and (equation 9); and of the development of an engine more efficient than any of those experimented with. The writer may repeat what he said in his article "Gear Box Design" in *The Automobile Engineer* for November, 1915, that "the information which is given here has no absolute significance, as it is based purely on the comparative method. This method enables us, by a detailed study of the existing examples, to evolve fresh ones of more perfect type."

In motor car and aviation engines we deal with a working mixture of air and gasoline (naphtha and kerosene in other types of engines) previous to combustion, and with burned gases after combustion. The determination of conditions of the burned gases, that is, the investigation

of the process of burning itself, in the engine cylinder from the moment when the working mixture is drawn in until the moment the spent gases are exhausted from the cylinder, is one of the most important problems. It is necessary to bear in mind the different factors influencing this process.

1. Those most familiar to the designer are: Shape of combustion chamber, cooling, location of spark plugs, valve timing, etc. Problems relating to these factors are mastered by the designer at the present stage of engine development.

2. The factors which are fairly well understood but which, nevertheless, require further investigation and improvement, include the volumetric efficiency, thermal and mechanical efficiency, suction temperature.

A third group of factors influence the burning process and the conditions of the burnt gases. To this group belong

3. Composition of working mixture, composition and specific heat of burned gases, the change of the number of gas molecules.

### Volumetric Efficiency

It is impossible to obtain working conditions that would allow the burned gases to be completely removed from the cylinder and a fresh mixture at 0°C and a pressure of 1 atmosphere to fill the whole volume of the cylinder for the suction stroke.

The realization of such conditions is prevented by the resistance which the mixture encounters in passing through the pipes and valves before it enters the cylinder. This is illustrated by Table I\* containing data of an actual test of a 200-hp. aviation engine, showing the vacuum in the inlet pipe at different speeds of revolution.

TABLE I

R.p.m.	Hp.	Suction in Inlet Pipe	
		Mm. of water	In.
1510	248	240	9.5
1510	234	420	16.5
1450	205	750	29.5
1360	163	1400	55.0

\*Le Moteur a Explosions by Rene Devillers.

The back pressure of the remanent gas in the combustion chamber, the temperature of the fresh mixture and possibly the fact that the inlet and exhaust gases flow in a series of waves and not in a steady stream, tend to keep down the amount of charge entering. The length of the wave depends on the length of the inlet pipe and does not always correspond to the period of the opening and closing of the valves. The closing of one of the valves causes the formation of a reverse wave in the inlet pipe, analogous to the wave of a stream of water inside a pipe which is suddenly stopped by a check. The pressure created in this manner depends on the length of the wave and the velocity of the gas at the moment of closing the valve.

### Values Obtained by Experiment

High speed engines possess a great advantage in this respect, as there is a possibility of making use of the inertia of the gas in the inlet pipe.

The reduced m.e.p. at the maximum engine speed as compared with the m.e.p. at low and medium speeds, prevents to a great extent any dangerous disturbance of gases in the inlet pipe and produces at the same time the necessary filling of the cylinder at the time when the maximum power of the engine is required.

Theoretically the volumetric efficiency (at  $P_0$  and  $T_0$ ) may be as high as  $\eta_v = 0.82$ . In practice, the volumetric efficiency generally does not exceed 65 per cent.

Experiments made by Prof. Riedler with three types of engines gave the following figures:

TABLE II

Engine	R.P.M.	Thermal Efficiency	Volumetric Efficiency
Daimler-Knight . . . . .	1920	20%	69%
96 x 130 . . . . .	(500—2100)	(18.5—21.5)	(88—65)
Daimler-Knight . . . . .	1920	16.57%	58%
101.6 x 129 . . . . .	(500—2100)	(16.0—19.4)	(81—52)
Adler . . . . .	1920	22%	64.5%
86 x 135 . . . . .	(500—2100)	(18.0—22)	(73—62)

### Theoretical Thermal Efficiency

The theoretical thermal efficiency of the four-cycle engine is usually expressed by the formula:

$$\eta_t = 1 - s^{n-1} \quad (1)$$

in which  $s$  = compression ratio, i. e., the ratio

$$\frac{V_h + V_c}{V_c} \text{ (Fig. 2).}$$

$$n = \text{ratio } \frac{C_p}{C_v} = 1.30 - 1.40.$$

$C_p$  = specific heat at constant pressure.

$C_v$  = specific heat at constant volume.

The thermal efficiency depends upon the compression ratio and  $n$ , but does not depend upon the temperature.

In this case the specific heat is supposed to be constant, i. e., there is no loss of heat; the expansion continues during the whole stroke and the charge consists of pure air. These conditions, of course, differ from those of actual practice. The specific heat of the working mixture increases with the increase of temperature;  $C_v$  (specific heat at constant volume) is not constant, but changes so the value of  $n$  changes and the thermal efficiency declines.

This change of specific heat is one of the most important points the designer must deal with.

The working mixture and exhaust gases consist of a number of perfect gases, including  $O_2$ ,  $N_2$ ,  $H_2$  and  $CO$ ; of carbon dioxide ( $CO_2$ ) and of water vapor ( $H_2O$ ). Of all the perfect gases  $CO_2$  exhibits the greatest increase in specific heat with a rise in temperature; of  $H_2O$  the increase of the specific heat is still more rapid, therefore, the presence of  $CO_2$  and  $H_2O$  will change to a great extent the specific heat of the working mixture, diminishing the value of the b.m.e.p. as well as the explosion temperature and pressure. As a result of experiments we assume a linear relation between the specific heat at constant volume and the temperature of the gas.

The maximum temperature of combustion depends on the strength of the mixture (air-gasoline ratio) and on the temperature of the entering charge. The change in the specific heats at high temperatures causes a loss of heat. There is loss of heat to the cylinder jackets, which depends to a certain extent on the number of revolutions of the engine. A high-speed engine has an advantage in this respect as the loss due to cooling is a function of the time, and the reduced time of cooling reduces the percentage of heat loss.

Therefore, the average loss due to the change of specific heat (17 per cent) to the cylinder jacket (16 per cent) and delayed combustion (3 per cent) in such a case amounts to about 36 per cent and the maximum possible thermal efficiencies for different compression ratios are:

Compression ratio	$\eta_t = 1 - s^{n-1}$	Theoretical thermal efficiency
4:1	38.4%	25%
5:1	43.1%	27.6%
6:1	46.6%	30%

It follows from the above table that the theoretical thermal efficiency for a compression ratio of 5 amounts to only 63.5 per cent of the air cycle efficiency (equation 1) although in practice it rarely surpasses 24 per cent (for  $s = 5$ ).

One of the principal aims in designing the engine, is to diminish the weight and increase the power. By reducing the weight of the flywheel, pistons and connecting rods, increasing the compression ratio and modifying the valve timing, we may increase the power, sometimes by 50 per cent, and diminish at the same time the noise and wear. The mechanical efficiency limits the speed of revolution of the engine, and as an increase in speed increases the power it is very important to determine the mechanical efficiency by experiment. The following valuable diagram made by Prof. Walter Fishleigh\* gives the value of mechanical efficiency as 0.62-0.85 for a 6-cylinder,  $4\frac{1}{2} \times 5\frac{1}{4}$ -in. engine at 640, 1,000 and 1,350 r.p.m. (Fig. 1).

The remaining factor of group 2, the inlet temperature, we will consider together with group 3 factors.

Coming now to the determination of the necessary data for constructing the theoretical indicator diagram,† we must first analyze the combustion process itself.

Prof. W. E. Grinevetzky of the Moscow Technical Institute, in his editorial supplement to the Russian translation (1907) of Güldner's Internal Combustion Engine, using the kilogrammolecule (kg.mol.) for the working mixture and burnt gases and taking as a base the molecular mean specific heat of gases, developed the formula for calculating the explosion temperature. The writer has applied the suggestion of Prof. Grinevetzky in calculating and constructing the theoretical indicator diagram of an engine, which gives sufficient knowledge of the relation of all factors of the working process and serves afterwards as valuable material for comparison with the real indicator diagram. Therefore, we will express the amount of the working mixture and burnt gases in kg. mol., taking as a unit the number of kilograms equal to the molecular weight of the gas.‡ By Avogadro's law, equal volumes of all gases at the same pressure (density) and temperature, contain the same number of molecules, i. e.,

$$1 \text{ gr. mol. of gas} = 22.330 \text{ liters.}$$

$$1 \text{ kg. mol. of gas} = 22330.00 \text{ liters.}$$

Such a unit contains a given number of molecules for equal volumes of all gases. The use of such a unit is very practical and identical to the measurement of volume.

The amount of air required to burn one kilogram of fuel, in kg. mol., is  $A/28.89$ , where 28.89 is the weight of a kg. mol. of air (this is also the molecular weight of air). The total number of kg. mol. of working mixture previous to combustion is

$$\frac{A}{28.89} + G$$

where  $G$  is the number of kg. mol. of the evaporated part of fuel, which may be considered as equal to zero, because the quantity of evaporated fuel drawn into the cylinder before the combustion may be taken as negligible. Therefore, we may say, that the total number of kg. mol. of working mixture will be:

$$\frac{A}{28.89}$$

Besides the fresh working mixture drawn into the cylinder

\*From a paper on Heat Balance Tests of an Automobile Engine, read at S. A. E. Meeting.

†The theoretical indicator diagram of the process AEZC (Fig. 2) compression and expansion follow the lines AC and EZ according to the equations  $Pv^{\gamma} = \text{const.}$ , i. e., polytropic.

‡A given body may be divided both chemically and mechanically. The infinitesimally small particles of an elementary material that can be divided no further either mechanically or chemically, are known as atoms. It is assumed that in any given material these atoms are closely associated in certain groups, and such smallest possible atom groups into which the material can be subdivided without affecting its chemical constitution, are called molecules. In other words, a molecule is the smallest weight necessary to enable a substance to maintain its identity, while the atom is the smallest conceivable weight with which the chemical elements form combinations.

Fig. 1—Mechanical and thermal efficiencies at three different speeds

Engine 6 cyl.  $4\frac{1}{2} \times 5\frac{1}{4}$ " L head type

A, A', A"—Mech. eff., fuel cons. and b.h.p. therm. eff. at 640 r.p.m.  
B, B', B"—" " " " " " 1000 r.p.m.  
C, C', C"—" " " " " " 1350 r.p.m.

der, there is a certain quantity of burnt gases remaining from the previous explosion.

Assume that  $\psi$  is the ratio of the number of kg. mol. of remanent gases to the working mixture, or the ratio of their volumes at equal pressure. Hence the total number of kg. mol. of gases in the cylinder previous to combustion is

$$\frac{A}{28.89} (1 + \psi) \quad (2)$$

Knowing the values of  $A$  and  $\psi$ , we may determine the quantity of gas previous to the combustion, and from the reactions of the combustion, we find the quantity and the composition of the burnt gases.

The working mixture and exhaust gases consist of perfect gases (di-atomic), including oxygen, nitrogen, hydrogen and carbon monoxide; of carbon dioxide and water vapor.

As the specific heats of the different gases are affected differently with an increase in temperature, let  $K_1$ ,  $K_2$ , and  $K_3$  be the numbers of kg. mol. of these three components of burnt gases obtained from 1 kg. of fuel. We assume a linear relation between the specific heat at constant volume and the temperature of the gas, and base our calculations on the mean specific heat of gases for changes from 0° abs. to the given temperature.

The molecular mean specific heat at constant volume may be represented by the following equations:

$$\left. \begin{array}{l} \text{For perfect gases} \dots\dots C_{v_1} = 4,625 + 0.00053 T \\ \text{For CO}_2 \dots\dots\dots C_{v_2} = 6,774 + 0.00189 T \\ \text{For H}_2\text{O} \dots\dots\dots C_{v_3} = 6,855 + 0.00116 T \end{array} \right\} (3)^*$$

The specific heat of masses of burnt gases from 1 kg. of fuel will be (equation 3).

$$C_{mv} = K_1 \times C_{v_1} + K_2 \times C_{v_2} + K_3 \times C_{v_3} \quad (4)$$

Substituting in equation (4) the value of  $C_{v_1}$ ,  $C_{v_2}$ ,  $C_{v_3}$  from equation (3) and  $K_1$ ,  $K_2$ ,  $K_3$ , we obtain the form of equation

$$C_{mv} = L + MT \quad (5)$$

As besides the working mixture in the cylinder there were some dead gases (equation 2) the total specific heat—

\*At the constant pressure:  
for perfect gases  $\dots\dots C_{p_1} = 6,600 + 0.00053 T$   
for CO<sub>2</sub>  $\dots\dots\dots C_{p_2} = 8,749 + 0.00189 T$   
for H<sub>2</sub>O  $\dots\dots\dots C_{p_3} = 8,830 + 0.00116 T$   
 $C_{mp} = K_1 \times C_{p_1} + K_2 \times C_{p_2} + K_3 \times C_{p_3} \dots\dots 4A$

# The Pfalz Single-Seater Fighter\*

## PART III

### Seating Arrangement—Aileron, Elevator, and Rudder Controls— Landing Gear

THE seating accommodation of the Pfalz does not present any special features, except, perhaps, that the pilot's cockpit is quite roomy considering the area of the cross section at this point. This is, of course, a consequence of the peculiar body construction, which, for a given cross section, leaves more space inside than is possible when employing the girder type fuselage with rectangular main structure and the fairings added afterwards. Thus, in the case of a circular cross section, for a diameter of 3 ft. the inscribed square is only about 2 ft., while with the monocoque construction the whole circle is available for the accommodation of the pilot. This is another way of saying that the cross sectional area of a body of rounded section can be kept smaller with monocoque construction than with girder-cum-fairing construction, resulting in lower head resistance.

The seating itself is of the usual type. The front edge of the seat is supported on the sloping former, while the rear of the seat rests on a transverse member supported on a small false former slightly farther aft. Needless to say, the pilot is equipped with a safety belt, which in the Pfalz is in the form of webbing, attached as shown in the illustration, to the longerons through a short length of coil spring.

\*From *Flight*.

Sketches of safety belt attachment

The Pfalz controls are shown in one of the sketches. A tubular control lever, forked at its lower end, is attached to a longitudinal rocking-shaft, which carries at its front end the transverse cranks for the aileron controls. In connection with these it should be remembered that ailerons are fitted to the top plane only, hence two cables pass from each end of the crank and around pulleys, one of them being what might be termed the positive cable, running through the lower plane, over pulleys, and to the aileron crank; the other being the return or equalizing cable running across the body through the opposite lower plane, over a pulley, and to the opposite aileron.

As is now general practice, means are provided for locking the elevator in any desired position. In the Pfalz (see cut) the collar carrying the aileron control cranks has welded to it a vertical forked lug, a bolt through which forms the pivot for a hinged stay rod, terminating at the top in a flat, curved, slotted strip, which may be locked in any position by means of a locking disc of aluminum. At its upper end the control column has welded to it two handles, bound with cord, of which the left is rotatable and operates the throttle, much after the fashion of a motorcycle. Centrally placed are two triggers operating the two synchronized machine guns through Bowden cables. A sketch is shown of the handle. This sketch, it may be pointed out, has been drawn from the port side in order to better show the twisting handle, while the general sketch of the controls is drawn as seen from the starboard side.

The rudder bar of the Pfalz presents some rather unusual features. Thus the rudder cables are anchored to forked lugs on the front of the foot bar, through which they pass, and issue from the rear of the bar through

Perspective drawing of Pfalz controls

channel section guides which act, when the foot bar is moved to the extremity of its travel, as quadrants for the cables. The object of this rather complicated arrangement is not clear, unless it has been done in order to get the forked lugs working in compression instead of in tension. The foot rests are in the form of flat forks inserted in sockets in the foot bar and provided with adjustment for length to suit individual pilots.

Where the rudder and elevator cables issue from the interior of the body they pass through small sheet steel plates carrying a steel tube fitted with a copper tube line to protect the cables against wear.

### Engine a Mercedes 160

The engine, a 160-hp. Mercedes, is mounted in the nose of the body on two longitudinal bearers supported by four main formers. The details of the mounting do not call for any comment, and the general arrangement of the engine mounting will be sufficiently clear from illustrations in previous instalments. The main fuel tank is carried in the bottom of the body, resting on the spar roots of the lower plane built into the body as a permanent fixture. The usual hand-operated pressure pump and an engine-driven pump are provided for forcing the gasoline from the main tank up into the service tank built into the top plane. The oil tank is carried by the side of the engine. The nose of the machine is rounded off, and terminates in a "spinner" fitted over the propeller boss, thus forming a very smooth entry for the air. Near the nose of the machine there are two scoops, that on the port side carrying air into the engine housing, while the scoop on the starboard side has a tube running to an opening in the crankcase, which is ventilated by this means. These features, as well as the neat inspection doors provided in convenient places on the front part of the body, are illustrated herewith.

Control handles of the Pfalz. The left-hand handle is rotatable and operates the throttle through a Bowden wire

Guide tubes for the rudder and elevator control cables

The undercarriage is of the Vee type, with stream line section steel tube. The struts look somewhat spidery, being of rather small dimensions as regards section. The major axis of the section is 1.89 in., and maximum thickness of the strut, occurring fairly back, is 1.18 in. The fineness ratio is therefore low. The attachment of the chassis struts to the fuselage is of interest. The rear struts are bolted (see cut) to an I section steel bracket built into the wing root of the body. Thus the landing shocks are transmitted through this strut through the bracket to the fixed rear spar of the fuselage, and to the sloping former surrounding the pilot's seat. The upper ends of the front struts are welded to elongated base plates of heavy gage, which serve as lugs for the chassis bracing cables. In order to distribute landing shocks over a larger area a steel plate is passed underneath the bottom of the body, so that the whole bottom part of the fuselage is attached to the struts in the loop of this strap.

### Landing Gear Cross-Braced

The apices of the chassis Vees are connected by cross struts, one in front and one behind the axle. In fact, it is hardly correct to term the rear a strut, as it consists of short lengths of solid tapered to fit the steel socket attaching it to the fuselage struts, the remainder of its length being made up of a thin strip of wood forming the top surface of the landing edge, while its bottom surface is in the form of a sheet of three-ply passing under the axle to the cross strut. The latter is a wood strut spindled in a "D" section, and tapered at the ends to fit the fuselage steel sockets which connect it by means of bolts to the chassis struts. The top of the stream-line casing of the axle thus formed is a hinged lid of aluminum, which, as the axle moves up and down when the machine is landing along the ground, opens and closes, lying snugly against the rear cross strut when the fuselage is relieved of its load as the machine leaves the ground, thus forming a good stream-line section with it, it is presumed, a fairly low head resistance. Cross bracing the chassis is in the form of stout stranded cable. As in the case of wing cables, no stream lining has been attempted. This feature is fairly typical of German machines of every design.

The shock absorbers are in the form of cords

Sketch showing nose of the Pfalz body, with spinner, air scoop and inspection door.

General view and details of Pfalz landing gear

as regards outward appearance, might easily be mistaken for rubber cord, but which on closer examination are found to be spiral springs, one inside the other, enclosed in a woven cover similar to those employed for covering stranded rubber cords. These springs are wrapped around the apex of the chassis Vee and around the axle, and are prevented from slipping up along the chassis struts by lugs welded to the struts. Two lugs higher up serve as anchorage for the short loop of stranded cable which limits the travel of the axle. This length of cable is enclosed in a cover to protect it against wear. The tubular axle is a fairly large diameter—2.16 in., to be exact; but we have not been able to ascertain of what gage the tube is made. The details of the under-carriage are shown in the perspective sketches herewith.

## An Instrument for Testing Permanent Magnets

THE magnet-meter, marketed by Herman A. Holz, Metropolitan Tower, New York City, is an instrument designed for testing permanent magnets of horseshoe or U shape for their total flux and for their coercive force. Flux and coercive force tests may also be made with the well-known instrument known as the permeameter, but the latter is not designed for, and cannot be satisfactorily employed in, determining whether or not magnetized shapes satisfy definite requirements.

A diagrammatic illustration of the magnet-meter is shown herewith. The principle of operation may be briefly described as follows:

A coil capable of rotary movement, to which is attached a pointer, traversing a calibrated scale, is supported between two specially shaped iron pole pieces. This movable system and scale are enclosed in an air-tight housing. The pole pieces are extended through the housing into contact faces

or plates, to which the polar portions of the magnet under test are applied. When a definite current is allowed to flow in the moving coil, a deflection of the pointer occurs which is proportional to the flux in the magnet applied to the contact faces.

In measuring the coercive force of the magnet, two adjustable solenoids are employed, which are located in front of the contact faces so as to encircle the respective legs of the test magnet. If current is allowed to flow in the proper direction through the windings of these solenoids, when the pointer is deflected in reading the flux, the deflection may be reduced to zero by regulating the current. The value of the current flowing when there is no flux is a direct measure of the coercive force.

Measurement of the flux does not affect the magnetization of the magnet under test, and this measurement therefore may be applied to every magnet in a lot. On the other hand, the measurement of the coercive force involves demagnetization of the specimen; and the latter has to be remagnetized after the test. In consequence the coercive force test would be applied only to a number of selected specimens.

Current for the moving coil is supplied from a dry cell and the current for the solenoids from a 6 or 12-volt storage battery. Contact shoes are provided to permit of ample contact between the polar portions of the test magnet and the contact plates, in

cases where the ends of the magnets are finished. No bushings are required to adjust the instrument for testing different sizes of magnets. The standard apparatus accommodates magnets of horseshoe type of any section of material up to 17/32 in. in thickness and 2 in. in width, with a minimum gap of 1 11/16 in. The price of the complete outfit, including the magnet-meter, milli-ammeter, ammeter, three rear staffs and two switches, is \$450. The instrument should be of interest particularly to magneto manufacturers.

Magnet-meter outfit

# The Nuttall Tractor Transmission

Gives Two Forward Speeds and Reverse—Enclosed in Well Ribbed Cast Iron Housing—May Be Readily Adapted to Different Designs of Tractors

**A** WELL designed transmission for agricultural tractors is manufactured by the Nuttall Gear Co. of Pittsburgh, Pa. While the transmission is produced in only one size, various changes are made in the design to adapt it to different types of tractors. The transmission is inclosed in a substantial, well-ribbed cast iron housing, so that the shafts are rigidly supported without the whole gear being unduly heavy.

The Nuttall transmission affords two forward speeds and one reverse, speed changes being effected by shifting gears laterally into mesh. The transmission comprises, in addition to the gearing for changing the speed and direction of motion, a power take off for the belt drive and a jack shaft with differential, the whole being inclosed in the cast iron housing referred to. All of the gears are made of forged steel, hardened and ground. All shafts are forged steel, hardened and ground, and all are mounted on flexible roller bearings.

The case in which the gears and differential are carried is a standardized unit, which it is seldom necessary to change in order to adapt the transmission to any particular tractor. The only parts which are somewhat different in transmissions made for different tractors are the bull pinion shaft and the housings which support them, the power shaft, and its housing.

The Nuttall transmission may be used with either a longitudinally or a transversely mounted engine, and the two constructions are illustrated herewith. In one case a short shaft extends into the transmission housing from the front, and carries the bevel pinion, meshing with another bevel pinion on the splined shaft, whereas in the other case the splined shaft extends entirely through the housing and is provided at its outer end with a sprocket wheel, or connected directly to the engine, as the case may be. With either type of engine the transmission may be mounted either in a horizontal plane or in an inclined plane. It is possible to provide the front end of the case with a bell housing, which may be connected directly to the engine bell housing, thus making of the engine and transmission a unit power plant. This arrangement is particularly desirable where a disk clutch is used, as this makes absolute rigidity necessary.

Although designed for 3-4 plow tractors, which are generally equipped with engines of 15-30 hp. ratings, the Nuttall transmission is claimed to be well able to transmit 42

hp. at 800 r.p.m. of the engine. Its average weight is 500 lb. The bearings which carry the power shaft are interchangeable end for end, which permits of the power shaft extension being placed on either the right hand or the left hand side. Where the front drive arrangement is used, that is, with a longitudinally mounted engine, slight variations in speed are possible, which are obtained by changing the number of teeth in the bevel gear and pinion. The design also permits of placing the bevel gear on either the right hand or left hand side of the bevel pinion, thus permitting the use of either an internal or external bull gear.

Some tractors have single wheel drives, and these do not require a differential gear. In this case only one bull pinion shaft is used, to which is keyed the main driving gear, and the differential gears are omitted. In the case of a chain drive, sprockets are used in place of bull pinions, but the transmission is mounted the same as for the gear drive.

In the design of the Nuttall transmission, efforts have been made to distribute the load due to gear action among the different bearings as nearly equally as possible, so that no bearings shall be subjected to an excessive load. The shifting mechanism, which works on the selective principle, is provided with a safety lock, making it impossible to have both sets of gears in mesh at the same time. For mounting the transmission on the frame, the housings of the jack shaft are provided with lugs, which can be bolted to the frame, and there is also a lug on the outboard bearing of the power take off shaft.

Standard Nuttall transmission for bull gear drive

*Vertical section through new Nuttall transmission*

Where the engine is mounted cross-wise on the frame, the housings for the jacketshaft on opposite side of the transmission housing are made of unequal lengths, so that the transmission comes close to one side member of the frame. The splined shaft of the transmission is then directly connected to the clutch shaft in line with the crank shaft.

Where the transmission is mounted at an angle fore and aft, or when the tractor is on a grade, there is a tendency for all the oil to flow to the lower end of the case. To prevent this partition walls are cast in the bottom of the case, which hold the oil under each set of gears.

*Side view of new Nuttall transmission and rear axle*

Quite recently the Nuttall Co. has completed a new tractor gearset intended for tractors pulling three or four plows. The gearset is a live axle design suitable for wheels up to 50 in. in diameter. It gives a gear ratio of 51.8 to 1 on low gear and 36.5 to 1 on high gear. With 50 in. rear wheels this gives a low speed of 2.4 m.p.h. and a high speed of 3.5 m.p.h.

The company is not yet completely tooled up for production on this new job, but in 60 days should be starting production and by Jan. 1 should have an output of 10 per day.

The gearset is a compact design in two parts, the transmission, which embraces the differential and rear axle drive shafts, and the forward end, which has a separate housing enclosing the bevel gears for driving the belt pulley. This separate portion bolts on the forward end of the gear box and has a bell housing end for bolting to the engine crankcase.

All gears are forged, including the large gears on the inner ends of the axle drive shafts, which are hydraulic forgings of 40-50 carbon steel.

The set complete weighs 1385 lbs. and affords three reductions. All shafts are carried on Timken bearings. The set of bevels driving the belt pulley are locked to the longitudinal shaft by a sliding clutch. The pulley shaft, together with its two Timken bearings, is a unit bolting direct into the side of the forward housing. The forward shaft of the gearset is splined and carries the two live gears, the differential being on the secondary shaft which transmits through two large gears on the divided rear axle. These drive shafts are  $3\frac{1}{4}$  in. in diameter.

# Dorris Two-Ton Truck Model K-4

Detachable Cylinder Head Doing Away with Valve Cages, One of the New Features—Three-Point Suspension Used Throughout—  
Final Drive Through Worm Gear

A NEW 2-ton truck model of the Dorris Motor Car Co., St. Louis, Mo., has reached the production stage. The Dorris company has been building 2-ton trucks since 1911, and, like its previous trucks and passenger cars, the new truck has a valve-in-the-head engine.

What appears to be the principal improvement of the new engine is a detachable cylinder head, which affords greater valve accessibility and eliminates valve cages. With the valve seats directly in the cylinder head, the water can circulate all around them and thus insure adequate cooling of the valves under all operating conditions.

The new engine has a cylinder bore of  $4\frac{1}{4}$  in. and a stroke of  $5\frac{1}{2}$  in. This is equivalent to 312 cubic inches piston displacement and to a N. A. C. C. rating of 28.9 hp. On the block the engine is said to develop 38 hp. at 1090 r.p.m. It shows a maximum torque of 175 lb.-ft. One of the notable features of the engine is its five-bearing crankshaft. This has a diameter of  $2\frac{1}{4}$  in. Of the main bearings the four forward ones are 2 in. long each, while the rear is  $2\frac{9}{16}$  in. long. The connecting rod bearings also are 2 in. long. All bearings are of the bronze-backed nickel babbitt type and are  $\frac{3}{16}$  in. thick. The same as the crankshaft, the camshaft is supported on five bearings, and therefore is very rigidly mounted.

## Aluminum Crankcase

The crankcase is cast of Lynite aluminum alloy and is formed with five heavy ribs to support the main bearings. This design lends itself to a very rigid construction, and it also facilitates adjustment of the bearings. The lower half, which forms the oil well and contains the oil screen, is also cast of aluminum alloy. Helical gears serve for driving the camshaft from the crankshaft, and these are of an exceptional width of face ( $1\frac{1}{2}$  in.). The valves, located in the cylinder head, have a clear diameter of  $1\frac{1}{8}$  in. and a lift of  $\frac{11}{32}$  in. They are made of tungsten steel. To insure positive valve action and at the same time smooth seating under extraordinary conditions of motor load, each valve is provided with two springs.

Lubrication is by force feed to all of the main bearings and to the connecting rod bearings, the crankshaft being drilled diagonally for this purpose. A continuous oil bath

Front view of Dorris truck

is provided for the valve mechanism and timing gears. The oil bath also serves to lubricate the spherical pivot supports of the push rods, which latter are adjustable by removing the pressed steel housing covering the rocker arm mechanism.

After experimenting with a variety of engine governors the Dorris company, in its new K-4 model, has incorporated a governor of its own design, which is built integral with the engine. It is completely enclosed, adjustable and seal tight, besides which it is claimed to give perfect governing and to be trouble proof. The engine speed is governed at 1090 r.p.m., which corresponds to a truck speed of 15 m.p.h.

## Three-Point Support for Engine and Gearset

A radiator of the vertical flanged-tube type with a cast shell is used, and increases the radiating capacity of former truck models by 25 per cent. The radiator is customarily mounted on the engine, and with the three-point support the latter it is well protected against frame distortion under road shocks. Back of the radiator is mounted a 20-in. flywheel which is driven by a 2-in. belt. In this new truck the Dorris company adheres to its former practice of three-point engine support.

The Stromberg model M-2 carburetor with duplex

Side view of Dorris 2-ton truck chassis

control and U tube is fitted. In connection with this carbureter is used a hot spot manifold, and easy starting and high fuel economy are claimed.

The clutch is of dry-disk type, and is built into a unit with the engine. It comprises seven disks, and affords a smooth, easy clutch action, together with a positive drive under all load conditions. The gear box is of the four-speed type, and is mounted separately amidships, one of the advantages of this mounting being unusual accessibility. Like the engine, the gear box has a three-point support, whereby it is protected from all frame distortion. The gears are made of 3½-in. nickel steel, and the whole transmission is enclosed in an oil-tight case.

From the gear box the power is transmitted to the rear axle through tubular drive shafts, fitted with large Spicer universal joints, the drive being so arranged that when the truck carries a complete load the various elements are in alignment.

### Pressed Steel Frame

The frame is built up of cold pressed steel channels, made from hot-rolled stock, these channels having a section 6 in. deep with 2½-in. flanges of ¼ in. thickness. The front axle is a drop forging of I-beam cross section, and the steering knuckles are mounted on Timken roller bearings. The rear axle is provided with the Timken-David Brown worm drive, and is completely enclosed in a reinforced pressed steel housing.

Left hand drive and center control are features of the new truck. In addition to the hand lever for throttle control, there is a foot accelerator. All control levers and pedals are of extra size and strength. The steering gear is of the worm and double nut type, which can be adjusted for wear.

*Engine of the Dorris 2-ton truck*

*Five-bearing crankcase*

Chrome vanadium steel springs are fitted, the front springs being 42 in. long by 2½ in. wide, and the rear springs 56 in. long by 3 in. wide. In the rear springs the second leaf is wrapped around the spring eye, insuring rigid construction and eliminating to a large extent all danger of spring breakage. The driving thrust and torque reaction are both taken to the rear springs, and a number of parts and their weight are thus eliminated.

### Equipment

The regular equipment furnished with the Dorris model K-4 comprises an oil pressure gage, a shaft-driven speedometer, oil side and tail lamps, driver's seat with Marshall spring construction, foot-operated horn, jack and complete set of tools.

If it is desired by the customer, an electric starting and lighting equipment may be readily installed, provision being made by the Dorris company for a Westinghouse 2-unit starting and lighting system with Bendix drive, in connection with a Willard storage battery. The battery furnished is of unusually large capacity.

The weight of the chassis complete is 5200 lb., and the chassis is furnished in two lengths of wheelbase, 144 in. and 162 in. The Dorris company is concentrating on this one model, for which it believes there is a large field, as the truck is of sufficiently rugged construction to permit of carrying as much as three tons under certain favorable conditions, and it is not too heavy to make its use advantageous where only one to one and one-half tons of pay-load have to be hauled.

### Experiments on Heat Dissipation

EXPERIMENTS have been made by the Engineering Department of the National Physical Laboratory on the effect of surface roughness on the heat transmitted from hot bodies to fluids going over them. The results of experiment for determining the heat transmission to water from the internal surfaces of brass pipes, smoothed and rough, showed that with the amount of roughening obtained the heat transmission per unit surface per degree difference of temperature between the metal and water for the smooth pipe could be increased in the ratio of about 2.5 to 1 for the same mean velocity of flow. It was obvious that if improvement of this order could be made in surfaces of air-cooled engines and radiators, considerable economy in material could be effected in aeroplane engine design. To test this out, a series of copper flanges of the form and distribution commonly adopted in air-cooled engines were fixed to a cylinder of the engine and set up in a wind channel. An electric current from a storage battery was then circulated through the flanges, and from measurements of the current and resistance it was possible to obtain the temperature of the flanges and the heat dissipated. The flanges were first tested in their ordinary smooth condition, and were then roughened by means of corrugated steel dies. In these experiments the roughening appeared to produce practically no effect on the heat transmission, this result indicating that the convection to the rough and smooth surfaces was approximately the same in each case.

### Investigation of Woods for Struts

TESTS have been made by the British Advisory Committee for Aeronautics on half-sized stream line struts, in order to compare the values of different kinds of wood for this purpose. Each strut was tested with an axial end load, and by the use of compound knife edges each end of the strut was free to take up any angle or position then under test. The modulus of elasticity for each material was found by a bending test, and this value was used to calculate the critical load to cause indefinite bending, according to the Euler theory for a simple strut. The agreement between these critical loads calculated from the dimensions of the strut and the modulus of elasticity of the material and the observed loads causing failure was remarkably good, indicating that the end constraint obtained with the special device adopted was negligible.

## HORSELESS AGE SUBSCRIBERS

Subscriptions for the Horseless Age transferred to the subscription list of AUTOMOTIVE INDUSTRIES in the merging of the two publications will be completed in full by the weekly issues of AUTOMOTIVE INDUSTRIES to the dates of expiration shown on the records of the Horseless Age Co.

Owned by United Publishers Corporation, Address 243 West 39th St., New York; H. M. Swetland, President; Charles G. Phillips, Vice-President; W. H. Taylor, Treasurer; A. C. Pearson, Secretary.

Entered as second-class matter Jan. 2, 1903, at the post-office at New York, New York, under the Act of March 3, 1879.

Member of the Audit Bureau of Circulations.

Automotive Industries-The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907.

## Tractor Standards Urgently Needed

NOW that serious attempts are being made to specialize in the manufacture of tractor parts, there is urgent need for further standardization. We fully realize that it is impossible to work out the fundamental problems of tractor design at the conference table, but much can be done to facilitate the manufacture of tractors designed in accordance with the present state of the art.

A point in question is the width of engine supports. Manufacturers of tractor transmissions must provide a shaft for the belt pulley, with a suitable housing and outboard bearing. If there were certain standard widths of engine supports, each covering a considerable range of engine power, the manufacturer of the transmission could make the pulley shaft a given length and be tolerably certain that it would fit practically every tractor frame. At the present time the engine makers have no standards to work to, and the widths between supports

range in a large number of steps between 18¾ and 26 in. There seems to be no reason why three sizes, say, 18, 22 and 26 in., would not serve all purposes. The former would not serve all purposes. The former would be used for the smaller and the latter for the most powerful engines, and all engines of substantially the same horsepower rating would have the same width at the supports.

It is this state of affairs that is holding back specialized development of tractor units. At present a great many tractor concerns are turning out tractors only in small numbers, and if the parts maker has to design his castings, etc., especially for each make of tractor, much of the advantage of specialized manufacture is lost.

Another subject which requires further attention is that of bell housings. These have been standardized for automobile engines, but owing to the greater strain on the housings of an unsprung machine, and especially on those housings which also form the supporting framework of the tractor, these standard housings have proved to be of inadequate strength. It is necessary for tractor purposes to use larger bolts than are provided for by the present standard, and they should be further removed from the inside edge of the flange.

The S. A. E. has made a beginning in tractor standardization, but so far little of any real consequence has been accomplished. This is no doubt due, in part, to a certain apathy of the old-line tractor manufacturers. The tractor industry, however, is entering a new stage, and a strong demand for standardization in certain lines is developing. The business of parts concerns is directly affected by standardization, and they will help the movement along in every possible way.

## Farm Lighting Outfits

THE farm-lighting outfit is a natural development of the electrical equipment for automobiles. It is true that farm-lighting outfits were proposed before automobiles generally became equipped with starting and lighting systems, but most of them left much to be desired from the viewpoints of reliability and economy.

The automobile electric system constitutes really a complete electric lighting and power plant, automatic in operation, and after the problem of such a system had been fully solved it became evident that the farm-lighting-outfit problem also was capable of a satisfactory solution. Many of the details of the farm outfit, of course, would differ essentially from those of the automobile system. Weight is not an important factor, but the economy of operation must certainly be better than that of the automobile system, which in spite of being relatively inefficient does not waste much energy because very little is actually used.

The earliest farm-lighting systems consisted of slow-speed stationary gas engines, connected by belt to the generator. Automobile influence on farm-lighting outfit design may be seen in the almost universal adoption of high-speed engines for these out-

fits—not strictly high speed in an automobile sense, but certainly high speed as compared with the old-style stationary gas engine. In fact, the speed of the engine has been brought up to a point where the engine can be direct-connected to the generator without the necessity of making the latter of inordinate size.

The advantage of a direct-connected unit over a belt-driven one is apparent. Not only is the need for a belt done away with, but the amount of floor space required is greatly reduced. In fact, where a belt-driven outfit requires a whole room, the direct-connected outfit may be placed in one corner of a room.

Engines of electric farm-lighting outfits are regulated for constant speed, usually by means of a throttle governor, and the problem of voltage control therefore is quite a simple one. On the other hand, certain safeguards must be provided to protect the battery against abuse. The farmer at certain seasons of the year is very much occupied with his field work and unless the outfit is so worked out that it pretty nearly takes care of itself, it is apt to prove unsatisfactory.

## What the Law Requires Is Not Enough

**W**HEN it comes to things which the law requires in the way of plant design and equipment, just meeting the legal requirements is, more often than not, less than what the wise and prudent manufacturer will do and not by any means all that he should do now.

What the law specifies is usually a minimum and at best it is a compromise between necessity and desirability. It is something that can be worked out in all cases and therefore not all that can be done to good advantage in most.

We are thinking now more particularly of health and safety provisions and can say, while the thought is with us, that the fact that there are such laws is, in a way, a sad commentary on our intelligence. From a more enlightened point of view they might seem like compulsory measures calculated to make us profit through the benefits which they insure. But be that as it may, the point of our present argument is that the material benefits to be derived from a liberal and intelligent provision of the things which the law prescribes fully warrant the investment and make it good business in most cases to meet the law and go it several better.

It has been repeatedly demonstrated that production is stimulated to a large extent by the very things which it has been found necessary to incorporate into law. It has been shown conclusively that the health of the worker is a matter of monetary importance to his employer. We may well quote again "Without health there is no energy, without energy there is no output," and we can add the obvious conclusion that without output there are no profits.

The newer thought is that the responsibility—and

owing to the great world need for efficiency in production methods it is to-day regarded as a responsibility—of the employer is concerned not only with the conditions under which the worker works, but with the physical condition of the man himself as well.

What the law requires in health and safety provisions is not enough to-day, either from the point of view of the manufacturer or of the country as a whole.

## Putting Our Colleges on War Service Basis

**D**URING the past year a striking metamorphosis has taken place in our college life. Even before the United States entered the war, many students left college to become ambulance drivers, and when this country became a belligerent so many volunteered for service and later were taken by the draft that some institutions were forced to close their doors for want of students and others faced an almost equally critical situation. While some of the older institutions are largely supported by endowment funds, the majority of our colleges are dependent upon tuition fees for their support, and with the decline in attendance their income dwindled away.

It is of the utmost importance to the nation that its institutions of higher education should be maintained through the period of the war, and the arrangement which has just been made, whereby the Government takes over the colleges and uses them for training men used in various capacities in connection with war work, is, therefore, to be hailed with approval.

In view of the immense amount of engineering work required at this time, much of which is of an entirely new character, intensive engineering training is quite essential, and under the new arrangement it will be given to those men in the draft who show most aptitude for such training. It is understood that the students will be picked mainly from the new class between the ages of 18 and 21, which embraces the usual range of age for entering college.

It is to be presumed that owing to the selective methods the student material will be of a better grade than normally, and the intensely practical nature of the courses to be offered should lead to results that will prove of great value to the nation.

Engineering is, of course, only one of the branches of instruction to be given during the war period. The colleges will also prepare men for infantry, artillery and machine-gunnery, naval and medical work. In fact, the Students' Army Training Corps, as the body of men enrolled in the Government's college courses will be known, will form a source of supply of skilled men from which all the various branches of our fighting and auxiliary forces can meet their requirements. As regards the class of service, the personal preference of the students are to be considered.

## Detroit Factories on War Work

### Passenger Car Manufacturers in That District Average 75% on Munitions

DETROIT, Sept. 17—War work is steadily increasing in volume in this territory and production of passenger cars is gradually diminishing. Speaking generally all passenger car manufacturers are 75 per cent on war work. While some have entirely suspended the manufacture of passenger cars, others are still engaged to 50 per cent of their facilities on commercial production. Many, however, although working on a very decided curtailment program, have a small percentage of war work in their plants. All the larger companies are in excess of 75 per cent on war work.

The Toledo plant of the Willys-Overland, Inc., is on a 75 per cent basis, while both the Elyria and Elmira plants devote 80 per cent of their facilities to government work. From a daily production of 425 cars in June, the output of the Willys-Overland has decreased to 200 cars a day. The plant is engaged in making gun carriages and shells, and recently received an order for 3000 Liberty 8's, for which it is tooling up.

The Saxon Motor Car Co.'s plant is devoting 25 per cent of its facilities to building trucks with the resulting reduction in passenger car production of 50 per cent since June. The company has a present output of twenty-five passenger cars daily. Paige, Reo and Maxwell are on a 75 per cent, Columbia Motors 60 per cent, Dodge about 90 per cent and Harroun 50 per cent war work basis.

General Motors Corp. and Chevrolet are on a 65 to 75 per cent war basis and orders for the Government are said to aggregate \$125,000,000. The Oakland Motor Car Co. is the only unit of the General Motors that has no war work. The General Motors Truck Co. is devoting almost its entire plant to war work, about 90 per cent of its facilities being engaged directly on trucks for the Government.

Willys-Overland, Inc., war orders are reported to aggregate more than \$50,000,000, and those of the Maxwell Co. are equally as great.

While both the Ford and Packard plants are on 100 per cent war basis, the plants of the Dort Motor Car Co. and King are working only on commercial production at the present time, the latter company having finished its contract for Government ambulances a short time ago.

The commercial production of passenger cars of the following companies averages 25 daily: Dort, Hudson, Paige and Saxon. The King output is four and the Columbia seven. The Scripps-Booth Corp. has reduced its production 50 per cent since July; it now builds 20 cars a day.

### Studebaker to Stop Production

SOUTH BEND, IND., Sept. 18—Special Telegram—Production of Studebaker passenger cars will stop as soon as the present stock of materials has been worked up. This announcement was made to 150 Studebaker dealers who gathered here to-day to get an outline of the company's relations in regard to them. Jan. 1, 1919, is the date set for the termination of passenger car work, from which time on the concern will concentrate on 100 per cent war work. The company is erecting some 300 homes in this city for workers to be employed in the shell plant, which also will be in operation about the first of the year. The continued rendering of Studebaker service was regarded as essential, and the furnishing of parts and replacements will be carried on as heretofore through the customary channels. The company's intentions are to give Studebaker owners the best of service.

### Hackett Suspends Operations

JACKSON, Sept. 11—The Hackett Motor Car Co., owing to difficulties in procuring materials to maintain production, has suspended operations.

### Jobbers Abandon Fall Convention

CHICAGO, Sept. 19—Special Telegram.—The National Association of Automobile Accessory Jobbers has called off its fall convention. This was to have been held in Medinah Temple, opening Oct. 28 and closing Nov. 2. The abandonment of the convention follows the decision not to hold the automotive equipment exhibition which was scheduled for the same building during the holding of the convention.

### Wolfe Leaves Goodyear

AKRON, OHIO, Sept. 17—William S. Wolfe, formerly assistant chief experiment engineer of the Goodyear Tire & Rubber Co., has entered the service of the maintenance division of the Motor Transport Corps.

### Dayton Wright Co. Builds 1000 Airplanes

DAYTON, Sept. 16—The Dayton Wright Aeroplane Co. has built its thousandth airplane. Six thousand operatives are now employed in the plant.

## New Labor Service Created

### Plans Drafted for Organizing a Training and Dilution Section

WASHINGTON, Sept. 17—The Department of Labor authorizes the following:

In order to stimulate production of war supplies through the organized training of workers, to increase the competency of wage-earners and to point out ways for rendering the existing supply sufficient through dilution, the Department of Labor has drafted plans for the organization of the Training and Dilution Service.

These plans have been made after a survey of the general industrial situation. Consideration has been given existing facilities for training workmen, and a study has been made of the supply and demand for skilled workers. Incidental to the stimulation of production is the protection of wage-earners against exploitation through unnecessary dilution of labor, guarding of established trade customs and standards against needless relaxation, and, where these trade customs and standards have been relaxed, the provision of means for restoring just standards.

This service will assist all departments of the government. In addition, it will help many industries to secure more and better trained workers, when such help will benefit war production. It will also suggest improvements in training methods relating to processes, occupations and trades; will propose to factories improvements in organization that will increase output through better working conditions; will draft plans so that manufacturers may train workers, and will organize and conduct such courses of instruction. This work will be done either directly or in co-operation with the Federal Board for Vocational Education, and with state and municipal school authorities.

In order to render more effective the work of the Training and Dilution Service, a close connection is being perfected between it and the production departments of the government (Ordnance, Quartermaster's, Air Service, Navy Department and others), so as to secure prompt action when war contractors are in special difficulties which may be relieved through the training of workers. District Superintendents of Training are being appointed.

Whenever a contractor applies for help in questions of labor, this superintendent will be instructed to visit the plant. After a consideration of the conditions at that plant, and if conditions are favorable, the superintendent will organize for the employer a special training department, select competent trainers from his regular force of instructors, or suggest competent instructors from lists which the Training and Dilution Service is compiling.

Educational facilities for the instruction of employment managers have been maintained during the past few months at several universities, the first having been offered by the University of Rochester. The United States Employment Service of the Department of Labor has assisted in financing these courses in employment management; and the Director of Training and Dilution has acted with the committee in general charge of the instruction. These courses are deemed so important that both the Training and Dilution Service and the Employment Service hope to increase the number of courses now offered.

In the Dilution Service a section on "Needs and Supply" will study sources of new labor and its applicability to industries, co-oper-

## Car Factory Labor Disturbed

### Seek Ruling Regarding Essentiality of the Work—The Revised Regulations

WASHINGTON, Sept. 18—Following the recent draft registration many of the passenger car factory employees hastened to leave this industry for others more directly termed war work, and to prevent disaster to the industry, Hugh Chalmers, representing the manufacturers, has been in Washington this week taking up this matter.

He attempted to have the passenger car placed on the preference list, at least until the end of the year. For various reasons the War Industries Board decided against this. It was, however, explained that the preference list is no absolute guide to the District Boards, which have complete power to decide individual cases and the status of individual industries.

It was further stated that the preference list does not guide the "work or fight" order but is merely used to determine deferred classification for occupational reasons.

In other words the men entitled to deferred classification because of reasons other than occupational will not be drafted under the "work or fight" rule unless they enter under the five classes which Provost Marshal-General Crowder named last spring and which included such occupations as clerks in mercantile establishments, persons engaged in sports, etc.

As a result it is advised and will be suggested in a letter by the N. A. C. C. to the manufacturers that every manufacturer should make an affidavit to the District Board to the effect that he manufacture passenger cars, trucks or both, that he has specified war work in his plant, if this is so; and he is advised to say that it is absolutely necessary to keep certain employes for work on passenger car production until the inventories are balanced as per the agreement between the N. A. C. C. and the War Industries Board.

It is also suggested that the individual employee who is essential should make an application for deferred classification and file it with the Board together with affidavit of his company and a copy of the agreement of August 24 between the N. A. C. C. and the War Industries Board.

It is believed that since the manufacturers must be allowed to continue, to fabricate the materials on hand and complete production or suffer great financial

injury, that the District Boards will heed the pleas. These Boards are governed largely by the decisions of an Advisory Board which investigates the merits of the different industrial exemption claims and which are comprised of a member nominated by the Department of Labor, one by the Department of Agriculture and one by the District Board.

Following is an extract from the revised selective service regulations which explains in detail the consideration given the preference lists issued by the War Industries Board and the methods of determining industrial exemption:

District boards are charged with the duty of selecting the individuals whose engagement in industry, including agriculture, or whose occupations or employments are such as to require their continued service in civil life rather than in the army.

In order to provide for the necessary adjustments between the necessities of the military establishment and the requirements of the industries, occupations, and employments, including agriculture, found to be necessary to the maintenance of the military establishment, the effective operation of the military forces, and the maintenance of the national interest during the emergency, there shall be appointed by each district board three persons to be known as industrial advisers to the district board.

One such person for each district board shall be nominated by the Department of Labor, one by the Department of Agriculture, and one by each district board, who shall thereupon be appointed by the respective district boards.

Whenever, in the discretion of the President, more than three such industrial advisers are required by a district board, the President may call upon the Department of Labor, or the Department of Agriculture, or the district board to nominate such additional industrial advisers, who shall thereupon be appointed by such district board.

Such industrial advisers so appointed by each district board shall not in any sense be members of such district board, shall have no right to vote at any meetings thereof, and shall have and exercise only the rights, duties, powers, and functions herein specifically given.

Such advisers shall have the right to furnish all pertinent information to the district board and may attend meetings of the board upon request of the board to which they are attached.

Such advisers may place before the district board at its meetings, or at such other time as the board may request, all facts and information in their possession as to the preference lists issued by the Priorities Division of the War Industries Board. Such lists shall not be regarded as binding upon the district board in its conclusions as to whether or not any particular industry, occupation, or employment, including agriculture, is a necessary industry, occupation, or employment within the meaning of the law and regulations, nor shall such lists prevent the district board from holding as necessary any industry, occupation or employment, including agriculture, not contained therein. Such preference lists and other facts and information in the possession of such advisers will supplement the information in the possession of the district boards and will also be used to assist the district boards in dealing with specific cases.

### Investigate Tin Stocks

WASHINGTON, Sept. 18—The War Trade Board has requested concerns in this country to make statements of the tin plate held in stock for exportation to foreign buyers or for sale to exporters who have orders from foreign buyers.

## Senate Favors Air Department

### Recommends Passage of Bill Creating Secretary of Aeronautics—Amendments

WASHINGTON, Sept. 18—The Senate bill to create an executive Government department to be known as the Department of Aeronautics and for the appointment of a Secretary of Aeronautics was reported favorably to the Senate by the Committee on Military Affairs yesterday. Several amendments were filed and it was recommended that the Senate pass the bill.

Following is the original bill and the report containing the amendments and recommendation:

### Text of the Bill

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, that there is hereby created for the period of the present war and for one year thereafter an executive department in the Government of the United States to be known as the Department of Aeronautics, the head of which shall be designated the Secretary of Aeronautics, who shall be appointed by the President and confirmed by the Senate. He shall be a member of the Cabinet and shall receive a salary of \$12,000 a year. The Secretary of Aeronautics shall have direct and complete control of all matters pertaining to the designing, purchase, manufacture, and production of aircraft and aircraft equipment intended for use of the Army, the Navy and the Marine Corps of the United States.

That the department shall also have an Assistant Secretary, who shall be appointed by the President and confirmed by the Senate, who shall receive a salary of \$5,000 a year; and such other officers and employees as may be found necessary for the proper and efficient transaction of the business of the department.

That the unexpended balance of such appropriations as may have hitherto been made for the purchase and manufacture of aircraft and aircraft equipment and all appropriations which may hereafter be made for such purpose shall be available for the purposes of the department.

### REPORT

The Committee on Military Affairs, to whom was referred the bill (S. 4852) to create an executive department in the government to be known as the department of aeronautics, and for the appointment of a secretary of aeronautics and an assistant secretary, and providing for appropriations for said department, having had the same under consideration, report it back to the Senate with the recommendation that it pass with the following amendments:

On page 1, line 9, strike out the words "shall be a member of the Cabinet," and

## New York Approves Anti-Glare Devices

Bulbs of Prescribed Candlepower Must Be Used to Comply with State Law

ALBANY, N. Y., Sept. 16—Secretary of State Francis M. Hugo has made public the names of 45 anti-glare devices which have been tested according to the provisions of the New York headlamp law and which are approved for use in New York State. However, it is essential, in order to comply with the requirements of the law, that they be used with headlamp bulbs of prescribed candlepower, and, in some cases, that headlamps be properly tilted. In the case of 20 devices, lamps need not be tilted.

The law under which these tests were made undoubtedly represents the first attempt of any state legislature to attack the headlamp glare problem in a scientific manner. Prior to the drawing of the law, the Secretary of State's office consulted with representatives of the Society of Automotive Engineers and the Society of Illuminating Engineers in an effort to obtain some basis upon which to determine the nature of glare and the best remedial measures. In consequence, a measure was drawn which prescribed that:

1—The candlepower of headlamps must be at least 1200 at a distance of 200 ft. in front of the car and at a point between the roadway and 42 in. above it.

2—The candlepower must not exceed 2400 at a distance of 100 ft. in front of the car and at a point 60 in. (or any higher) above the road.

3—The candlepower must not exceed 800 at a distance of 100 ft. in front of and 7 ft. to the center of the car at a point 60 in. above the road.

The devices which have been approved have been determined by tests to come within the requirements of the law when used with bulbs of a prescribed candlepower. In using these devices, Secretary Hugo suggests that dealers and owners:

1—See that the right candlepower bulb is used.

2—See that lenses are properly placed and not twisted; that the top side is at the top and that the front is outward.

3—See that the tilt is correct. To do this have the car on a level surface in front of a wall or some suitable vertical surface, 30 ft. or more distant. Remove the front glasses or devices and by means of focusing adjustments move the bulb back and forward until the beam of the smallest diameter is obtained on the wall. By measuring the height of the center of the beam from the ground and comparing that with the height of the center of the headlamps from the ground, the tilt can be ascertained and adjusted as required.

4—See that the bulb is properly adjusted with respect to the focus of the reflector with the controlling device in place. Do this by observing the beam pattern on the wall.

Herewith is the list of approved devices.

The term "B Lamp" in the accompany-

ing table refers to the usual Tungsten headlamp bulb. The term "C Lamp" refers to the gas-filled headlamp bulb.

### Urge Higher "Gas" Price for Canada

OTTAWA, Sept. 10—That an order-in-council fixing the retail price of gasoline in Ontario and the West is advisable, is a statement made in a report by R. J. McFall, High Cost of Living Commissioner, to Hon. T. W. Crothers, Minister of Labor, on the cost of gasoline, made public to-day. McFall suggests a ruling which would establish 36 cents as a maximum retail price in Ontario, 43 cents in Saskatchewan and 45 cents in Alberta. No changes are suggested in the wholesale price of gasoline, it being noted that the cost of imported gasoline has increased from 5/6 of a cent to 1½ cents a gallon because of increased freight rates and other causes.

### Mason Rubber Co. Gets War Order

KENT, OHIO, Sept. 14—The Mason Rubber Co. has been awarded a Government order for \$100,000 worth of gas masks and raincoats and it is anticipated that further war orders will be received.

## Gasoline Shortage in Argentina

75 Per Cent of Automotive Vehicles Laid Up in Storage Owing to Lack of Fuel

BUENOS AIRES, Aug. 15—There is practically a complete stoppage of the use of automobiles in Argentina, due to shortage of gasoline. Not only is gasoline selling at an exorbitant price but the actual lack of it is so great that conservative estimates say that 75 per cent of the automobiles are laid up and in storage in consequence.

This situation is acting very much to the detriment of the sale of American motor trucks, tires, accessories, automobiles and motorcycles. This is the winter season and bad roads always stop a percentage of cars from being used while the rainy season is on, but this year the situation is more acute than ever before in the history of the American automobile in Argentina.

Large distributors of American acces-

\*Manufacturer's adjustment.

sories, tires, etc., in Argentina declare that unless the present acute situation is alleviated promptly the results will be very damaging to the future of the American motor car and its accessories so far as their sale in Argentina is concerned.

The world war has given American commerce its first opportunity to obtain on a large scale a foothold in the Argentine market, and it behooves America to remove any obstacle that may prevent that foothold from gaining a solid foundation that will not give way under the powerful competition that is bound to come when the war is over.

#### Consumption of Gasoline Exceeds Production

WASHINGTON, D. C., Sept. 14—We are at present using 3000 bbls. of gasoline daily more than we are producing, according to Fuel Administrator Garfield, who has presented statistics to the Senate following the resolution introduced by Senator Lodge.

The figures, which were compiled by the Oil Division of the Bureau of Statistics, indicate a reserve supply for about 30 days. Mr. Garfield attributes the constantly diminishing stocks on hand to the heavy war demand.

Since April 1, when production was highest, there has been a decrease in reserves of 4,119,000 bbls. of oil. Since April there has been a daily deficit of 6000 bbls., which would indicate a deficit for the year of approximately 2,000,000 bbls. It is stated that stocks of crude oil are constantly declining and kerosene and fuel oil supplies are unsatisfactory, all of which bears an intimate relation to the gasoline problem. Following are the statistics covering stocks of gasoline in the East:

#### EAST OF CALIFORNIA

	Barrels.
Gasoline and naphtha stocks, 1918—	
Jan 1.....	8,400,000
April 1 (high point).....	11,000,000
Aug. 1.....	7,800,000
Decline in stocks.....	3,200,000
Estimated daily production and consumption:	
Approximate daily consumption—	Barrels.
Domestic.....	160,000
Export.....	34,000
Total daily consumption.....	194,000
Approximate daily production.....	191,000
Average daily deficit.....	3,000
(Probable result for year ending Dec. 31, 1918.)	

#### Wisconsin Branch of N. A. D. A. Formed

MILWAUKEE, Sept. 14—A Wisconsin branch of the National Automobile Dealers' Association was organized on a temporary basis at a meeting of State dealers which followed a luncheon tendered by the Milwaukee Automobile Dealers' Association at the Milwaukee Athletic Club on Sept. 11. Another meeting will be held in about a month, at which a permanent organization will be effected. Officers will be elected at that time. In the meantime, an organization committee consisting of one representative dealer from each of the twenty-one counties in Wisconsin will do local promotion work and conduct a membership campaign.

## A Balloon Target for Aviators

Released in the Air and Used Like a Punching Bag by the Flier

WASHINGTON, Sept. 16—A target resembling a cylindrical shaped balloon has been devised as a float target for airplane gunners. It is released in the air and is said to be to the airplane quite like the punching bag is to the boxer.

The new target is taken aloft by a cable attached to an airplane through the bottom of the fuselage and wound on a windlass. At 5000 feet it is released and allowed to float free. The airplane dives at the target, runs from it and uses every stunt, the barrel roll, the Immelmann turn, the side slip, nose dive and tail spin, while shooting at it. The target is at the mercy of the air currents and, being light in weight, twists and turns in every direction and manner, making it as tricky as a Boche opponent. Service ammunition is used by the gunner. This target practise is engaged in over uninhabited areas.

This form of target was devised by the instructors of the gunnery school at Rockwell Field, California, which is under the Division of Military Aeronautics.

## Automobile Trade in Shanghai, China

By R. W. Davis

SHANGHAI, CHINA, July 31—There are probably about 2000 automobiles of various kinds in Shanghai, all of which are used for utilitarian purposes. This is a goodly number when you think that the farthest point you can reach from Shanghai with an automobile is 8 miles from the center of the town. This road condition applies to nearly all cities in China, and consequently the use of the automobile is restricted to the conveyance of owners from the residential portions of Shanghai to their offices, an average distance of 2 to 3 miles. As China is very little affected by the war, any influence on the automobile industry that might be attributed to the war must be ignored, so far as conditions here are concerned. Native labor is so cheap that it is doubtful whether motor trucks or farm tractors could compete with it either in road transportation or agricultural work. There are a few motor trucks in Shanghai used for such purposes as electric cable repairing, fire department work, etc.

One of the greatest drawbacks in connection with American makers of automobiles for the Chinese field is their failure to provide handbooks or manuals giving every detail relating to the car and its operation. There are very few motor experts in China who have time to give instructions to buyers, the consequence being that the standard of driving and

caring for an automobile is very low. I would estimate that 75 per cent of the cars are driven by Chinese chauffeurs who are entirely ignorant of such niceties as proper breaking, gear-shifting, etc. The American automobile manufacturer who takes the trouble to have a book of instructions translated into Chinese for the use of chauffeurs would enjoy considerable advantage over others, apart from the direct advertising value which would come from such.

#### Federal Rubber Co. Makes 1000 Gas Masks a Day

MILWAUKEE, Sept. 16—The Federal Rubber Co. has reached a production of more than 1000 gas masks a day. Between 100 and 125 women are engaged in this department of the work and as soon as more help becomes available the number will be increased to at least 400. Throughout other departments of the plant, more than 300 women are now employed, they having taken the places of men who have entered the service. Another notable development of the war is that the Federal plant now employs twenty-five deaf mutes in the woodworking shop and rubber departments.

#### Safety Congress Meets at St. Louis

ST. LOUIS, Sept. 16—The seventh annual safety congress of the National Safety Council opened at the Hotel Statler to-day. The Automotive Section meets Friday. The program follows:

- 1—Report of Chairman.
- 2—Report of Secretary.
- 3—Reports of Committees.
- 4—Addresses:
  - Machine Shop Layouts and Their Relation to Safety, by C. A. Briggs, Safety Engineer, Willys-Overland Co.
  - Safety in Punch Press Operation, by W. W. Roach, Safety Department, Dodge Brothers.
  - Necessity of Inspection for Overloaded Floors, by D. R. Livingston, Supt. Safety Division Reo Motor Co.
  - Selling Safety to Employees, J. J. Lynch, Chevrolet Motor Co.
  - Gasoline in the Industries, When Used as a Solvent, by R. A. Shaw, Safety Department, Ford Motor Co.

#### Women Operating Farm Tractors in England

LONDON, Sept. 2—Women are proving very satisfactory and are rapidly replacing men in the operation of farm tractors in England. An official statement recently issued by the Food Production Department says that women are doing excellent work. It also reports that the Government has supplied on hire to farmers 4100 tractors and has arranged for the direct sale to farmers of more than 2000 more machines.

#### Kenly on Army-Navy Board

WASHINGTON, Sept. 14—Major General William L. Kenly, director of military aeronautics, has been detailed by the President as a member of the Joint Army and Navy Board of Aeronautic Cognizance, vice Major General George O. Squier, chief signal officer, relieved.

## Reopen Air Service for Induction

Both Mechanics and Officers Needed as Pilots, Armorers, Observers and Balloonists

WASHINGTON, Sept. 18—The Air Service has been reopened for induction of mechanics and of candidates seeking commissions as pilots, armorers, observers and balloonists, irrespective of status in the draft. Candidates are sought for this service, which has been closed for the past 6 months, because of its rapid and huge growth.

Twenty-nine flying fields have been completed in this country. More than 1200 deHaviland planes, 6000 Liberty engines, parts for the first heavy night bombers, 6600 training planes and 12,500 training engines have been completed and necessitate the increase of both the commissioned and enlisted personnel in order to maintain full strength in this country and continue the necessary flow overseas. There is fast movement overseas of air squadrons, planes, engines and material for American aerodromes, fields and assembly plants in France and England, according to a statement issued here to-day by the War Department.

The Air Service is to-day 160 times what it was at the outbreak of the war. On April 6, 1917, it numbered 1100 enlisted men regardless of cadets in training and officers as compared to 147,434 enlisted men on Aug. 1, 1918. Civilians have not been allowed to qualify as pilots since March, 1918. During last fall and the early winter 6600 prospective flyers, accepted by the examining boards, had been built up and has since been gradually drawn upon as the Service grew. In addition many of the enlisted men have been allowed to train for commissions.

Applicants may apply at the Aviation Examining Boards. The age limits for flyers are 18 to 30 years, inclusive, with preference to those under 25, and for balloonists from 18 to 45. The examining boards are located at:

Atlanta.....	Georgia School of Technology
Boston.....	739 Boylston St.
Chicago.....	230 East Ohio St.
Dallas.....	Camp Dick
Fort Sill, Okla.....	Post Field
Los Angeles.....	Marsh-Strong Bldg.
Minneapolis.....	University of Minnesota
New York.....	104 Broad St.
San Antonio.....	Fort Sam Houston
San Francisco.....	55 New Montgomery St.
St. Louis.....	525 South Euclid Ave.
Washington.....	Bldg. D, Floor 1, Wing 2
Canal Zone.....	Camp Sherman

The call for mechanics opens the Service to men anxious not only for active field work but also for the service for which their training best fits them. Skilled men only are wanted. Those accepted will be sent to a Concentration Depot, trade tested, given special intensive training in airplane mechanics and then organized into airplane crews and squadrons, some for duty here, others for duty overseas, with good opportunity

for advancement, since four-fifths of the men are promoted above the grade of private.

### Believe Electric Tax Unfair

WASHINGTON, Sept. 18—Electric truck manufacturers have filed a letter with the Ways and Means Committee asking for reconsideration of the proposed tax of \$5 per horsepower and 50 cents per 100 lb. weight. The manufacturers believe that this rate is too high. One objection has been that it is considerably higher than gasoline-driven trucks, on which the tax ranges from \$10 for 23 hp., \$20 on 30 hp., \$30 on 40 hp. to \$50 over 40 hp. Congressmen have answered this by saying that when the 2 cents per gal. tax is included, the gasoline-driven trucks pay an even higher tax than the electric trucks. This works out, for example, with a 5-ton 6-hp. electric truck weighing 5000 lb. paying a tax of \$30 on horsepower and \$25 on weight, or a total of \$55, as compared with a 5-ton gasoline truck of 40 hp. paying \$30 tax and consuming, say 10 gal. of gasoline a day, a daily tax of 20 cents, or \$60 a year. The electric makers do not believe this comparison is a just one. They state that there is a discrimination against electric trucks.

### Liberty Tractor Co. Organizes

The Liberty Tractor Corp., Detroit, has been organized with a capitalization of \$100,000. The incorporators are: Frank H. Farnham, John O'Donnell and Ignatius Mirkovich.

### Senate Favors Air Department

(Continued from page 513)

On page 1, line 12, strike out the word "and," and after the word "production" insert "and operation."

On page 2 add as a new section to the bill the following:

"Sec. 4. The President is hereby authorized to establish the necessary subordinate bureaus for the conduct of the operation of the department of aeronautics and to transfer to said department such functions, powers, and duties now vested by law in other departments of the government pertaining to the air service and such personnel necessary for its operation."

### New Labor Service Created

(Continued from page 512)

ating especially in this work with the Woman in Industry Service and other policy bureaus of the Labor Department, so as to maintain the unity of the government's labor policy.

Advice from the Working Conditions Service, of the Department of Labor, will be sought regarding industrial standards. At the same time the facilities of the Employment Service and of its Women's Division will be utilized in obtaining information as to the needs and the supply of labor. In return, the Training and Dilution Service will be able to assist the Employment Service in meeting the demand for skilled workers, which make up about 70 per cent of the labor calls of employers.

A section on "Industrial Hygiene," of the Training and Dilution Service, will be established to inquire into the conditions and suitability of particular factories for dilution.

Among the more difficult problems now confronting the Training and Dilution Service is the "following-up" of workers who have received training in order to assure proper surroundings for health, morals and efficient utilization of their ability. Another problem is that of the wastage of manpower. The Training and Dilution Service will study such problems as these with a view to pointing out methods that will minimize waste in industry due to overmanning.

## Mexican Mines Need Many Trucks

Admitted Duty Free at Present—Required to Replace Railroads Destroyed

MONTEREY, MEX., Sept. 9—Several of the larger mining companies of Mexico have placed orders for motor trucks recently. Shipments of trucks are beginning to arrive in Mexico for these concerns as well as for use of manufacturing plants in the City of Mexico. The irregularity of railroad traffic is necessitating the substitution of motor truck hauling wherever possible. In discussing the subject of Mexico as a market for motor trucks H. M. Gillespie, sales manager of the Southern Motor Co. of El Paso, who is familiar with conditions in this country, said:

"There is a great future for the truck industry in Mexico as soon as trade is again opened up with the United States under former international conditions of trade. Now that mining is picking up again, there is a greater demand for trucks than before the Mexican revolution, because many miles of railroad have been destroyed as well as thousands of cars. It is impossible for mine operators to get the ore to the smelters by rail as formerly and they must do it quickly. They have no time to wait until a railroad is rebuilt.

"Therefore trucks are in demand. At present trucks are admitted to Mexico free of duty, which greatly encourages the business. With a return to the old relations with our Mexican neighbors, as well as further settlement of internal conditions in Mexico, the truck trade in Mexico will quickly assume gigantic proportions."

### Curtailment of Non-War Industries

WASHINGTON, Sept. 12—The War Industries Board has arranged for the co-operation of the various State Councils of Defense in the matter of curtailing various non-war industries. The State Councils will make investigations and recommendations, and while these recommendations will not be final, they will play an important part in the decisions rendered by the board. The State Councils will investigate and report general non-war construction, but they will not enter into the undertakings of the War Department, Navy Department, Emergency Fleet Corp., Bureau of Industrial Housing and Transportation, United States Housing Corp. or the following civilian enterprises:

Repairs of or extensions to existing buildings involving an aggregate cost not exceeding \$2,500.

Roadways, buildings and other structures undertaken by the United States Railroad Administration.

Mines producing coal, metals and ferroalloy minerals.

Public highway improvements and street pavements which have been approved by the United States Highways Council.

Building projects not mentioned above will require special written permits from the Priorities Division of the War Industries Board. Any one contemplating a building which he believes to be in the public interest, or otherwise essential under the existing emergency conditions, should make a full statement of the facts in writing under oath, and present it to the Local Council of Defense, which will in turn take it up with the War Industries Board.

### Store Door Delivery for Philadelphia

PHILADELPHIA, Sept. 12—Covering delivery in this city of less than carload freight lots, the railroads, according to federal plan, in co-operation with the Chamber of Commerce, are putting into effect a "store door" delivery system. Consignees will have only 24 hr. in which to remove freight after it arrives. Failing in this, the freight will be loaded on motor trucks and delivered to the consignee at his expense for the hauling.

The Pennsylvania Railroad, under a new plan, whereby the city is divided into 14 shipping zones, will take all shipments consigned to the western destinations, as Harrisburg and beyond; the Reading, to the north and northwest, and the Baltimore & Ohio, to the south.

### Hupp Surplus \$1,176,262.50

DETROIT, Sept. 14—Net profits of the Hupp Motor Car Corp. for the fiscal year ending June 30 were \$836,691.30. Surplus fund was \$1,176,262.50 compared with \$431,124.30 for the same period last year. Total assets were \$8,939,789.91. Current assets showed cash on hand of \$731,165.70; accounts receivable less all doubtful accounts, \$762,877.94; bills receivable, \$12,764.35. Inventories based on cost totaled \$1,834,786.09, with securities, including Liberty bonds, aggregating \$173,860.36. The company had no outstanding bills payable. Accounts not due totaled \$749,645.52, tax reserve, \$279,971.28, and reserve customer deposits were \$215,910.61. A copy of the balance sheet follows:

ASSETS	
Plant Assets:	
Land .....	\$98,656.62
Buildings .....	866,242.41
Machinery .....	407,096.69
Factory equipment.....	414,995.53
Special tools, jigs, and patterns for current Models "Net".....	170,868.55
Furniture and fixtures.....	54,210.69
	\$2,012,070.49
Less reserve for depreciation.....	435,647.70
Total property investment.....	\$1,576,422.79
Note: The land, buildings, machinery and equipment were appraised by the American Appraisal Co. as of Dec. 31, 1916, as having a sound value of \$762,740.09 more than the value as shown on the books.	
Current Assets:	
Cash .....	\$731,165.70
Accounts Receivable:	
For cars protected by B/L drafts .....	\$476,221.89
For parts protected by B/L drafts and customers' deposits .....	180,089.21
Sundry debtors .....	106,566.84
	\$762,877.94
Less reserve for doubtful accounts .....	27,590.89

Work in process.....	260,345.85
Finished cars .....	57,821.10
	1,834,786.09

## Truck Builders Get Preferential List

### War Industries Board Lists Approximately 70 Industries and Over 6,000 Plants

WASHINGTON, Sept. 14—The National Automobile Chamber of Commerce has written to motor truck manufacturers announcing that the War Industries Board has issued a preferential list of industries which will be sent to them in a few days. The letter, which indicates the basis to be adopted for the classification of essential uses of trucks and the matter of deferred classification under the draft law, follows:

#### To Motor Truck Manufacturers:

1. The War Industries Board has issued a preference list of industries. This list includes approximately 70 industries and more than 6000 individual plants which are being added to from time to time.
2. A list of these industries will be sent you within a few days, and the list of 6000 individual plants can be seen in the custody of the local draft board or the representative of the U. S. Labor Bureau in your city.
3. The final revised list of industries, which is to be a guide for truck sales, we hope to forward within a few days.
4. Among the individual plants are or will be listed the approved manufacturers of motor trucks who have filed pledges and applications for places on the preference list. Necessary employees of such companies will be considered in essential work.
5. Manufacturers of passenger cars are being handled in another manner by the War Industries Board. They are being given certain priority for materials to match up their stocks of materials on hand under a curtailment program.
6. This list of industries and the 6000 individual plants will be the guide for essential uses for trucks, as agreed with the War Industries Board. This list may be used as a basis, but where any question arises as to the essential use of a truck, the matter should be referred for definite ruling to the Automotive Products Section of the War Industries Board, for submission to the Priorities Division.
7. This new preference list will not bind the district draft boards in allowing deferred classification under the draft law. Persons seeking deferred classification, whether they are employers or employees, will submit to the draft board whether they are so essential to industry that they should remain out of

military service. The draft boards will determine what industries are necessary and what employees are necessary to the maintenance of such industries.

8. The real purpose of the master key preferential list of industries is not to operate as an embargo against other industries not named, but "to defer the requirements of all other industries and plants until those on the preferential list shall have been satisfied."

9. Industries have been grouped into four classes. The classes differ in degree of necessity as vital elements in the prosecution of the war.

### Skilled Workers Still Critically Short

WASHINGTON, Sept. 14—Transfers of machinists and other skilled workmen from non-war work to war production through the United States Employment Service is increasing steadily, according to a statement made by the Department of Labor. The Employment Service has sent a number of examiners throughout the country to recruit skilled workers at non-war plants by patriotic appeals. The examiners comprise machinists, boiler makers and sheet metal workers.

The shortage of skilled labor in the war industry is considered critical. It is said that even if the non-war industries give up their entire organizations of skilled workers it is doubtful if the supply will meet the demand. It is estimated that not more than 25 per cent of the machinists in the country are still engaged in non-war work, and that some of these are unable to move to war industries centers because of family and other primary considerations.

The following skilled workers are most sorely needed in the order named: Machinists, boiler makers, riveters, chippers, calkers, molders, structural iron workers and coppersmiths.

### Glenn L. Martin Tests First Plane

CLEVELAND, Sept. 14—The first plane produced by the Glenn L. Martin Co. has been completed and has flown from Cleveland to Dayton for experimental tests with a crew of four men.

Investments in securities:	
Preferred stock purchased for retirement (in Treasury) .....	\$99,710.36

## Highway Labor Problems Under Jurisdiction of Chapin

WASHINGTON, Sept. 14—All labor problems coming under the United States Employment Service and which are in connection with highway utilization will be referred to the Highways Transport Committee of the Council of National Defense, which is headed by R. D. Chapin, chairman.

The committee will adjust all problems of labor as connected with transport activity, either power or horse drawn. This new additional work for the Highways Transport Committee is the result of a letter received from J. B. Densmore, Director General of the United States Employment Service, as follows:

The U. S. Employment Service recognizes the war-time need for making the most effective and efficient utilization of our highways as a means of strengthening and increasing our transportation resources, and especially is acquainted with the valuable direction given by the Highways Transport Committees to this problem.

We are also convinced that tonnage capacity of our highways transport resources can be greatly increased by applying all possible vehicles, horses and labor in line with national policies promulgated by you and, naturally, in transportation that vitally aids in accomplishing our war program.

We therefore desire to effect any adjustment of labor employed in any phase of highways transport activity, relating to either power or horse-drawn vehicles, in co-operation with your national organization, relying on your State Highways Transport Committees to furnish the facts regarding essential highways transport activity with which they are intimately familiar and on which our state and local labor department officers may base their necessary orders.

We are therefore transmitting instructions to our representatives, advising them that all matters touching or in any way affecting highways transport operations are to be dealt with on the advice of your organization.

### Seven Aviation Deaths

WASHINGTON, Sept. 14—Seven deaths resulted from aviation accidents in training at flying fields in this country for the week ended Sept. 7, 1918. This number represents one fatality for every 1469 hr. flown, or 117,520 miles of air travel. Following is the summary:

Barron Field, Everman, Texas.....	2
Kelly Field, San Antonio.....	2
Mather Field, Sacramento.....	2
Tallaferro Field, Fort Worth.....	1
Total.....	7

### Reo Prepares for Apprentice Course

LANSING, Sept. 14—The Reo Motor Car Co. is making preparations for the establishment of an apprenticeship course which will be opened early in October. John H. Amiss, for 7 years superintendent of the Lima Consolidated Schools, Howe, Ind., has been engaged as educational director. Shop mathematics, layout work, blueprint and mechanical drawing will be some of the studies taught in the class room. The course, as now mapped out, will require 3 years to

finish, the apprentice receiving at the end of this time a certificate which vouches for his skill as a mechanic. The age limit of the applicant has been set at from 16 to 19 years. The apprentice course is not confined to boys whose fathers may be Reo employees, but covers all applicants and is not as exclusive as the old course. Machines for instruction are being installed as well as benches and other equipment for the students' use. There are now fifteen applications filed for entrance, and when the school is in full swing the company will have at least 200 apprentices enlisted in the course.

### Girls in Cadillac Service Department

BOSTON, Sept. 14—Young women have been added to the mechanical department of the Cadillac Automobile Co. by Manager Albion L. Danforth. After giving the matter some thought, having put girls to work in the salesrooms where they proved efficient, he decided to try them in the service department. The first girl was put to work in the stock room supplying parts to customers. She did the work so well that the vacancy in service sales department caused by the draft was filled with another young woman. She proved very valuable and fitted into the position nicely, where she determines cash and credit transactions from her credit file at the time a job order is written, and keeps a record of all the movements of cars through the various departments of the building as well as answering numerous telephone calls. And the customers seem to like dealing with the young women, who are courteous and intelligent. Others will fill places made vacant from time to time.

### Massachusetts Pumps 100% Perfect

BOSTON, Sept. 14—The Massachusetts State Department of Standards has just finished an investigation of the gasoline pumps throughout the state to determine if motorists were receiving full measure these days. This is the second year an investigation was held, last year many pumps being found defective. By means of cars in which specially constructed glass tanks were placed, with measurements carefully marked, it was possible to drive up to any roadside pump, buy gasoline and in a minute determine whether it was perfect or imperfect. The department permits a variation of 6 cu. in., or about 5 table-spoons, in 5 gal.

This year Thure Hanson, director of standards, has announced that there has been a marked improvement, and that it may be said that the pumps in Massachusetts are practically 100 per cent perfect.

### Overland Gets Curtiss Engine Contract

WASHINGTON, Sept. 12—The Willys-Overland Co. has received a contract for 1500 Curtiss O. X.-5 airplane engines of the 8-cylinder type, to be used in training planes.

## Liberty-Engined Caproni Makes Climbing Record

NEW YORK CITY, Sept. 14—The Caproni bombing plane, fitted with three navy type, low-compression Liberty engines, has been getting tuned up for its official Government test, and this week has established some new climbing records for a bombing plane of this type, which has a capacity for carrying approximately 4000 lb. of bomb load. In its climbing test on Sept. 9 the Caproni climbed 3000 meters, or over 9000 ft., in 16 min. with a full load of gasoline and four men. This is a better climbing performance than this plane has ever made before, and is a new record for climbing with planes of this capacity.

### More Trucks in Massachusetts

BOSTON, Sept. 14—Taking Massachusetts registrations for Jan. 1 to Sept. 1 this year, and comparing them with the figures for the total of 1917, they show that of the increased machines registered this year for every passenger car listed there were registered 1 3/5 trucks, or 16 trucks for every 10 cars.

Last year there were registered in Massachusetts 148,266 cars. Up to Sept. 1 this year there were 151,818 cars listed, or 3552 more than the entire 1917 figures. For the 12 months of 1917 there were 26,008 commercial vehicles listed, and for the first 8 months of this year there were 31,649 registered, or a gain of 5641. That is 2089 more commercial vehicles than passenger cars.

If a comparison is made between the first 8 months of 1917 and the same period of this year the figures are 136,417 and 151,818 cars respectively and 24,025 and 31,649 trucks. That was 15,401 cars gained and 7624 trucks. However, if it were not for the big truck gain this year, representing some 32 per cent to 11 per cent for cars, the total registration for 1918 up to date would have fallen below the figures for the entire year of 1917.

### Road Oil for Army Camps

WASHINGTON, Sept. 12—The Fuel and Forage Division of the Quartermaster Corps will purchase 903,000 gal. of road oil for the Construction Division, for use at fifteen camps and cantonments in this country. This road oil is to be used to lay the dust around camp hospitals and upon drill grounds. About 10,000 tank cars will be required to deliver this quantity.

### Housing and Transportation

WASHINGTON, Sept. 14—Housing and transportation conditions have become so congested in some cities where war supplies are being manufactured that the General Staff has cautioned the purchasing agencies of the War Department to consider local conditions before placing contracts.

In each of the 60 congested cities the Bureau of Industrial Housing of the Labor Department has found it necessary to expend federal appropriations to relieve housing and transportation shortage.

In some cities the congestion is so great that the use of beds in three daily shifts has become imperative. This has created an exceedingly high labor turnover, delaying the completion of war work and increasing its cost.

It is not the intention to cut off new orders entirely from these districts but to regulate them. Where new plants require additional labor power or new structures or facilities are needed it will be the disposition of the General Staff to discourage such increases in these cities and to develop them elsewhere. The following cities are suffering from serious housing shortage:

Aberdeen, Md.	New Castle, Del.
Alliance, Ohio.	New London, Conn.
Alton, Ill.	New Orleans, La.
Bath, Maine.	Newport, R. I.
Bayonne, N. J.	Newport News, Va.
Bethlehem, Pa.	Niagara Falls, N. Y.
Bridgeport, Conn.	Niles, Ohio.
Butler, Pa.	Norfolk, Va.
Camden, N. J.	Pensacola, Fla.
Charleston, S. C.	Perth Amboy, N. J.
Charleston, W. Va.	South Amboy, N. J.
Chester, Pa.	Philadelphia, Pa.
Davenport, Ia.	Phillipsburg, N. J.
Dayton, Ohio.	Portsmouth, N. H.
Derby, Conn.	Portsmouth, Va.
Easton, Pa.	Puget Sound, Wash.
Eddystone, Pa.	Quincy, Mass.
Elizabeth, N. J.	Rock Island, Ill.
Erie, Pa.	Seattle, Wash.
Florence, Ala.	Sharon, Pa.
Hammond, Ind.	Sheffield, Ala.
Indiana Harbor, Ind.	Mariner's Harbor,
Jersey City, N. J.	Staten Island, N. Y.
Gary, Ill.	Tacony, Pa.
East Chicago, Ill.	Troy, N. Y.
Lowell, Mass.	Utica, N. Y.
Middletown, Ohio.	Warren, Ohio.
Milton, Pa.	Waterbury, Conn.
Moline, Ill.	Watertown, Mass.
Newark, N. J.	Watertown, N. Y.
New Brunswick, N. J.	

#### New Departure Mfg. Co. to Hold Field Day

BRISTOL, CONN., Sept. 16.—The New Departure Mfg. Co. will hold its annual field day, which will include an inspection of the plant, a sheep barbecue, a ball game, sports, a golf handicap, etc., on Sept. 21-22. The company's slogan is "We wish to conserve for ourselves and our help a spirit of good will and optimism, a pleasant place in which to live and work and an establishment to which our boys now at the front may return. In all else we Hooverize."

#### Goodyear Company Salvages \$3,000,000 in Year

AKRON, Sept. 11.—The Goodyear Tire & Rubber made in 1 year a salvage of \$3,000,000 worth of materials that might have been wasted were it not for the co-operation of its 20,000 workmen. This is a larger amount than the output of finished product of 98 per cent of the country's manufacturing concerns.

## Latin America Big Automotive Buyer

### Exports from New York Alone Total Over \$7,500,000 in Seven Months

NEW YORK, Sept. 16.—An analysis of the exports of passenger cars, trucks and parts to the various Latin-American republics for the seven months ending July, 1918, discloses some interesting figures, and indicates that, despite limited shipping facilities, manufacturers are not neglecting the opportunities offered by South and Central America, Cuba, etc.

During these seven months 5243 passenger cars, valued at \$4,771,654; 419 trucks, valued at \$751,222, and automotive parts, valued at \$2,020,696, were shipped from the port of New York alone, the aggregate value being \$7,543,572. Obviously the total exports to Latin America from the U. S. A. are considerably greater, as shipments have been made from a dozen or more different ports.

During the period under review Chile leads in passenger car purchases, partly for the reason that returning nitrate ships offer plenty of freight accommodations. A glance at the truck column suggests that there are good opportunities for the development of business in practically all the republics, more particularly as Latin-American business and finances are in a very flourishing condition and there is a general speeding-up of commerce to meet war demands.

#### Missouri River Boats Stop

KANSAS CITY, Sept. 14.—Navigation of the Missouri River between St. Louis and Kansas City was suspended for the winter, on Sept. 3, when a steamer with two barges arrived at Kansas City on its last summer trip. The equipment has been taken over by the federal authorities, and it will be used on the Missis-

sippi below St. Louis. The barges have brought many motor cars to Kansas City this summer and much stock for accessory dealers. All traffic trucks distributed from the Kansas City branch have been brought from St. Louis on the barges, in shipments of six to nine. The trucks are run onto the roofs of the barges at St. Louis, and run from the barges onto the wharves at Kansas City; here they are filled with gasoline, and taken to the distributing headquarters under their own power. The river shipment has saved some freight expense, but has been most economical in its saving of labor in loading into freight cars. There has also been a marked advantage in time, the river shipments reaching destination within 5 days of leaving factory, while by railroad the shipments would have consumed from a week to a month.

#### New York Routes Cars and Trucks

NEW YORK, Sept. 16.—The New York Police Department has adopted a new system of routing passenger cars and commercial vehicles through the principal streets of the city. The plan has been adopted to eliminate confusion and reduce congestion. The order restricts 22 thoroughfares, chiefly the main north and south avenues, to passenger or commercial traffic, 10 being exclusively for passenger cars and 12 for motor trucks. Motor trucks will be prevented from using the streets designated for the use of passenger cars, though their drivers may make deliveries or collections of merchandise on those streets by entering them at the nearest intersecting street.

#### International Harvester Merger Ratified

NEW YORK, Sept. 16.—The Internal Harvester Co. of New Jersey and the International Harvester Corp. have been merged and the two companies will be continued as the Internal Harvester Co. The capital is \$60,000,000 preferred and \$80,000,000 common.

#### EXPORTS OF AUTOMOBILES, TRUCKS AND PARTS FROM NEW YORK TO LATIN-AMERICAN COUNTRIES DURING SEVEN MONTHS ENDING JULY, 1918

## 413,000 Bbl. Gasoline Saved

### Two Gasless Sundays Add Materially to Reserve for Overseas Shipments

WASHINGTON, Sept. 16—Four hundred and thirteen thousand barrels of gasoline were saved by the observance of the first two voluntary motorless Sundays, according to the Fuel Administration. The Administration kept no records, but secured figures from the oil industries which took a count from 2 o'clock to 4 o'clock Saturday, Aug. 31, Sunday, Sept. 1, and Sunday, Sept. 8. In each instance there was an increased reduction on the second Sunday in the percentage of cars used. Illinois leads with counts of 20,000, Aug. 31, and 108 on Sept. 8, a reduction of 99 per cent. Reduction in every state exceeded 75 per cent. The Fuel Administration states that the gasoline saved has added materially to the reserves available for overseas shipments, for use in tanks, trucks and airplanes at the front. In answer to the question if gasolineless Sundays will be extended to include the territory west of the Mississippi, the Fuel Administration says it does not seem necessary, although it is possible. They are now canvassing the territory to determine the ability of the refiners to care for the West and at the same time provide the necessary gasoline at the Atlantic seaboard. If they cannot provide both demands the country west of the Mississippi will also be called upon to forego Sunday motoring temporarily.

#### Briscoe Corp. Adds to Plant

JACKSON, MICH., Sept. 14—The Briscoe Motor Corp. is erecting two additional buildings for the manufacture of war material. These measure 200 x 200 and 90 x 100 ft. respectively.

#### Government to Pay Cash

WASHINGTON, Sept. 18—All supply bureaus of the War Department will, hereafter, whenever possible, take advantage of cash discounts for the prompt payment of bills. Instructions to do so have just been issued by the General Staff. Contractors who have followed the custom of granting cash discounts to the public will be required to state in their proposals the amounts they will allow the Government for prompt payment of their bills. Where it has not been the custom to give fixed cash discounts the Government will request contractors to state how much they will allow for prompt payment. These discounts will be considered by contracting officers when making awards.

That the Government may be sure of such discounts in the future it is provided in the instructions that all materials and supplies shall, in so far as possible, be inspected and accepted by the Government at the point of manufacture or

origin. The Inspecting Officer is ordered to see that the proper vouchers are sent through promptly with the Government bill of lading attached, to the Contracting officer so that the bill may be paid within the specified time during which discounts will be allowed.

#### Truck Sales Directors to Form National Association

MILWAUKEE, Sept. 16—A national association of sales directors of American motor truck manufacturers probably will be permanently founded this week at a meeting to be held in Detroit, as the result of a conference attended by representatives of ten of the largest commercial vehicle factories of the country, which was held in Milwaukee during the past week. The Milwaukee conference was called upon the initiative of William H. Reese, advertising and sales manager of the Sterling Motor Truck Co., which entertained the representatives for two days. A temporary organization was formed and each delegate was appointed a committee of one to solicit the attendance of one other sales manager for the Detroit meeting this week. The purpose of the organization is to plan ahead for the time when not so much of the capacity of truck factories is required for Government work and the industry is better able to produce vehicles for ordinary commercial channels in sufficient quantities to meet the demand. Another aim is to insure a proper distribution of the trucks now available for commercial purposes to the end that each truck sold may be placed where it will do the most good.

## July Truck Exports Very Small

### Figures Indicate Our Export Trade in Motor Trucks Is Not Satisfactory

NEW YORK, Sept. 17—A glance at the record of automotive products exported during the month of July shows that although the figures covering cars and parts are normal, the number of trucks exported during the month is distinctly disappointing. It is true that France has taken a considerable number—there are very obvious reasons why she must do so—but apart from this the total for the month is so very small as to be almost negligible. As a matter of fact our truck exports for the month, including those sent to France, is little more than one-half the total value of those shipped abroad in June. Deduct the July deliveries to France and the remainder are valued at but \$237,330.

No doubt there may be a shortage of shipping from time to time, which, in part, accounts for the falling off, but the transportation problem is being solved and shipping is now a great deal better to Latin American and other parts than was the case a little time ago.

Every encouragement is being given by the Government to the development and maintenance of foreign trade. Truck builders are in a priority class as regards the supply of material for approved use.

#### AUTOMOBILE, TRUCK AND PARTS EXPORTS FROM NEW YORK FOR JULY

## Safety Congress at St. Louis

### 4000 Industrial Plants Represented—Special Automotive Sections

ST. LOUIS, Sept. 16—Almost 2000 delegates to the Seventh Annual Safety Congress of the National Safety Council registered to-day at the Hotel Statler. The Council represents about 4000 industrial plants and in his report W. H. Cameron, secretary of the Council, said:

"The total number of fatal accidents has been reduced one-third since this organization began its work. Five years ago 35,000 men and women were losing their lives every year in accidents, and the number of industrial accidents was about 2,000,000. With mechanical safeguards, supplemented by safety education in all plants, the number of accidents could be reduced not one-third, as it has been, but from 50 to 85 per cent, I believe."

The two big features announced for the first day of the convention were cancelled because Secretary of the Interior Franklin K. Lane and Charles M. Schwab of the Emergency Fleet Corporation telegraphed that they could not be present.

Mr. Schwab, who will speak on "The Democratization of Industry," will appear later in the week.

As a result of these cancellations, the first day was given over largely to business sessions and the reports of committees and the officers.

David Van Schaack of Hartford, Conn., director of publicity for the Aetna Insurance Co., who is president of the National Council, in his address at the opening session, dwelt upon the safety propaganda which the Council is now making its particular war—the introduction of safety instruction in schools.

Nearly 200 speakers, most of them representatives of the large industrial plants, are on the program for the five days, as the Congress ends Friday. At the dinner President Wilson will deliver a short address by telephone. There is a strong sentiment that some plan should be developed whereby the methods used by the Government in training maimed soldiers for new occupations should be maintained in the future for victims of industrial accidents.

The Automotive Section will meet on Friday. The program of that session is given on page 515.

The automotive industry also is interested in the "Public Safety" Section on Thursday afternoon, the program of which is as follows:

I. Automobile Headlamps, W. F. Little, Electrical Testing Laboratories, New York City.

II. Desirability of Uniform Signs and Signals, with Some Suggestions, John Gillespie, Detroit, Mich.

III. Public Accounts—What They Mean in Monetary Loss, A. W. Whitney, General Manager, Workmen's Compensation Service Bureau, 13 Park Row, New York City.

IV. The Classification of Public Accidents, Frederick S. Crum, Assistant Statistician,

Prudential Life Insurance Company of America, Newark, N. J.

During the week of the Congress here a very special effort is being made to eliminate all accidents in the city, both industrial and street accidents. Policemen, drivers and shop workers are asked to use every precaution to show how few accidents are necessary to a large community. Almost every motor vehicle is carrying a special sign.

### Airplane Assembly System Incorporated in Training Course

WASHINGTON, Sept. 17—A system of airplane assembly has been incorporated with the general training course at Kelly Field, Texas, for both cadets and student officers. This is a departure from the general curriculum, is not general and has not yet been approved by the training section. At present the work includes 12 days of instruction in putting together wings and fuselage only. The other parts of the plane will enter into instruction as the course advances, until the practical assembling of a complete airplane is a part of the instruction of every flier. It is expected that this will prevent carelessness, tendency to hurry the work or to overlook anything that may later endanger life. It will take the prospective flier completely through all the shops.

### Pier Exposition Opens

CHICAGO, Sept. 16—The Automotive and Accessories Exposition opened on the Municipal Pier Saturday. A big floor space is used on one-half of the big pier building and the management expresses the belief that the week will disclose a successful exposition.

There is a total of 106 exhibitors, 78 of whom show parts and accessories. There are six complete trucks shown, two truck formers, four farm tractors and four tractor parts, one industrial tractor, one road tractor, one house lighting system and ten miscellaneous displays, including the Red Cross, State of Wisconsin agricultural exhibit, Cook County School, and some farm papers.

The exhibit of agricultural implements was limited to two disks and a plow attached to the three Fordson tractors, shown by the Rue Motor Co. The other tractor displays included the New Craig tractor with its P-T wheel, which makes its first appearance at this show, the Inter-State tractor and the Happy Farmer.

The chief tractor part exhibit is that of the Foote Bros. Gear & Machine Co. with its planetary tractor gearset. The Mercury Mfg. Co. had one of its industrial tractors on display, and the One-Wheel Truck Co. had a road tractor.

Motor trucks shown are the Winter, Muskegon, Traffic, Forschler and Tower.

### Washington Office for Duesenberg

WASHINGTON, Sept. 16—The Duesenberg Motors Corp. has established a Washington office in the Munsey Bldg. It is in charge of General Sales Manager N. G. Rost.

## Tractor Curtailment Discussed

### No Decision Reached—Further Curtailment in Agricultural Implements Considered

WASHINGTON, Sept. 17—A preliminary meeting was held here yesterday by the War Service Committee of agricultural implements and independent tractor manufacturers with the War Industries Board with a view to further curtailing agricultural implements and possible curtailment to some extent of the manufacture of farm tractors. No decisions were arrived at, the greater part of the discussions being on the importance of farm tractors both among our Allies and in this country. The War Industries Board stated that independent tractor manufacturers were present. Names of those at the conference could not be obtained owing to the fact that Judge Edwin D. Parker, Priorities Commissioner, who presided, did not make a record of them.

The farm implement and farm operating equipment industry has already discontinued the manufacture of 3000 surplus types of plows and tillage implements, as was announced in an earlier issue of AUTOMOTIVE INDUSTRIES. Further reduction of this and possible reduction of tractors is being considered to further conserve iron and steel for other war needs.

### A Substitute for Glass in Aviators' Goggles

WASHINGTON, Sept. 17—The Medical Research Board of the Division of Military Aeronautics has found a substitute for glass for aviator goggles made of thin sheets, not glass, but which can be used as such. This substance has been on the market for some time, but the company which makes it has not heretofore been able to cast it in the right strength and thickness suitable for goggles. The substance is hard and non-inflammable and insures practically a non-shatterable lense for the protection of the pilot's eyes.

### Deferred Classifications for Transportation Employees

WASHINGTON, Sept. 17—Concerns engaged in the transportation within cities and along the public highways of necessary commodities can claim deferred classification for their necessary employees, according to a ruling made here to-day by the Provost Marshal General of the War Department. This means that a motor truck transportation company hauling merchandise or commodities essential to the maintenance of the military establishment, or the effective operation of the Army, or the maintenance of national interest during the emergency, can claim deferred classification in the draft for their employees providing they are necessary to them.

**Jarosch Leaves Bearings Co.**

LANCASTER, PA., Sept. 12—F. J. Jarosch has resigned as chief engineer of the Bearings Co. of America and become secretary and manager of the Liberty Engineering Co., Lancaster, Pa., recently formed for consulting, designing, research and development work. Associated with him are: President, J. E. Perkinson; vice-president, C. W. Lea, and treasurer, R. A. Heiland.

M. Bleiweiss has been appointed manager of the planning department and stores of the Templar Motors Corp., Cleveland. He retires from the Premier Motor Corp., Indianapolis, where he served as assistant to sales manager and assistant to factory manager.

Guy E. Tripp, formerly Colonel United States Army and head of Production Division, has been made Brigadier-General United States Army, and placed in charge of the production of ordnance material. General Tripp is succeeded as head of the Production Division by Colonel C. C. Jamieson.

Zeno D. Barns, who for the past 3 years has been connected with the Westinghouse Air Brake Co. as non-ferrous metallurgist, is now connected with the general operating department of the Aluminum Castings Co., Cleveland.

Fred W. Vormelker has been appointed efficiency engineer of the Russel Motor Axle Co., North Detroit, and will have charge of all work pertaining to the following departments: Time study, routing, factory time, employment and efficiency.

Charles M. Steele, formerly vice-president of the Carl M. Green Co., Detroit, who has been in this country on leave of absence for the past 2 mo., has returned overseas to continue his work with the Y. M. C. A. He is located in Paris and is in entire charge of the entertainment division of the Y. M. C. A. work in France.

**Memorial Road for Michigan**

DETROIT, Sept. 14—Willard M. Bryant, Kalamazoo paper manufacturer and field secretary of the Michigan State Good Roads Association, is the leader of a movement having for a purpose the building of a "Memorial Paved Way," 18 ft. wide and extending throughout Michigan for a distance of 300 miles.

It is to be a memorial in honor of the fallen soldiers of the state. The route proposed is through St. Joseph, Benton Harbor, Kalamazoo, Camp Custer, Battle Creek, Charlotte, Lansing, Owosso, Saginaw to Bay City. It is said that the project has met with the approval of many prominent men in the state and that it may result in a permanent organization being established to set the project under way.

## Men of the Industry

### *Changes in Personnel and Position*

**Sandusky Changes Personnel**

SANDUSKY, Sept. 14—The Dauch Mfg. Co., which produces Sandusky tractors, has made two changes in its personnel: L. E. Willson has been appointed general sales manager, and J. W. Wellington, general manager. Willson was formerly vice-president in charge of sales of the Briscoe Motor Corp., Jackson, Mich., and Wellington was formerly production manager of the New Castle (Ind.) plant of the Maxwell Motor Co.

Clay G. Howery, formerly associated with the production and purchasing departments of the Continental Motors Corp., Detroit, has been appointed general manager of the American Steel Supply Syndicate, Detroit. The management has been reorganized and the company equipped with an extensive screw machine and heat-treating department. The corporation is working almost entirely upon Government orders, manufacturing parts for engines.

George T. Bryant, formerly connected with the Russell M. Seeds Advertising Agency, has been appointed sales manager for the Hide, Leather & Belting Co., Indianapolis. This company manufactures leather belting and parts for cars, trucks and tractors.

Norval A. Hawkins, sales manager for the Ford Motor Co., has entered the United States Army Ordnance Department as an assistant to Major George D. Wilcox, who is in charge of the Motor Transport Service for the Detroit district. Mr. Hawkins has been granted leave of absence by the directors of the Ford company to permit him to devote all his time to Government work. He will resume his duties with the company when his services are no longer required by the Government.

**Furlough Essential Skilled Men**

WASHINGTON, Sept. 14—Companies engaged in war work who find that the draft is taking their skilled men in such numbers as to impair efficiency and seriously reduce production of war material may apply to William R. Ritter, War Industries Board, for the furlough of these essential skilled men. Investigations will be made by the Commodity Section Chiefs of the War Industries Board, and Mr. Ritter will decide regarding the furloughs following their recommendations.

**Emil Grossman in New Business**

NEW YORK, Sept. 14.—Emil Grossman, former president of the Emil Grossman Mfg. Co., has instituted a new business, styled E. G. Mfg. Co., located at 50 West 54th Street. The company's business consists of locating surplus stocks of automotive equipment and supplying jobbers whose stocks are short.

Samuel W. Prussian, president and owner of the Guaranty Truck Co., Cambridge, has accepted a position in the Quartermaster's Department for the duration of the war, although he is exempt from the draft because of his age.

Harry W. Ford, former president of the Saxon Motor Car Corp., Detroit, has gone to Washington and is associated with Colonel Barret Andrews in the reorganized Army Transport Corps under General Drake.

E. S. Ralph, for several years with the advertising department of the American Seeding Machine Co., Springfield, Ohio, has been appointed advertising manager of the R. & P. Tractor Co., Alma, Mich.

George C. McMullen has been appointed Western representative of the Timken Roller Bearing Co., with headquarters in San Gabriel, Cal.

W. H. Conant of New York, formerly manager of the Pittsburgh Motor Vehicle Co., is now manager of the Prismolite Co., Columbus, Ohio.

S. A. Campbell, formerly sales manager of the Warnola Mfg. Co., New York, is now associated with the Bay State Pump Co., Boston.

**American Motorcycles for Canadian Police**

MONTREAL, Sept. 13—Thirty-five motorcycles are being purchased for the police department, at a cost of between \$400 and \$500 apiece. Twenty will be Harley-Davidsons, obtained from the Art. Ross Co., and fifteen will be Hendersons, obtained from Graveline & Kennedy. Delivery of some of the machines has already been made.

**Lansing Forge Enlarges Plant**

LANSING, Sept. 12—The new addition to the Lansing Forge Co. is expected to be completed by Oct. 1. The new facility is 67 by 80, and will be used for dies and stock storage. The company took over the property of the old Emergency Drop Forge Co., which went into the hands of a receiver. The new organization consists of outside capitalists who make a special of the forging business. Many changes have been made in the old plant, which has been modernized in every way.

**Lease Old Pathfinder Plant**

INDIANAPOLIS, Sept. 15—The plant of the Pathfinder Automobile Co., which recently passed through dissolution proceedings, has been leased by the S. M. Dixie Shoe Polish Co. of Brooklyn, N. Y., and will be used for the manufacture of shoe polish.

**Indiana Truck Corp. Erecting Building**

INDIANAPOLIS, Sept. 15—The Indiana Truck Corp., Marion, is erecting a new building 70 x 200 ft. The building will be of fireproof construction. The company has recently received government contracts which have necessitated the increasing of its manufacturing facilities.

**Sun Plant Is Sold**

INDIANAPOLIS, Sept. 15—The plant of the Sun Motor Car Co., Elkhart, has been sold to W. L. Huffman, Omaha, who announces plans for establishing a company for the manufacture of motor trucks. The plant contains 60,000 ft. of floor space. The new owner has announced no plans as to the type of truck to be manufactured.

**Truck Man Adds Tractors**

CHARLES CITY, IOWA, Sept. 14—The American Engine & Tractor Co. has closed a contract with the Brehm-McMullen Co., Minneapolis, for 300 Matchless-American 15-30 farm tractors. The Brehm-McMullen Co. is Acme truck distributor.

**Smith Engineering Works Extends Plant**

MILWAUKEE, Sept. 16—The Smith Engineering Works has broken ground for a two-story machine-shop and office building, 67 x 100 ft., to cost \$32,500. The company is a large builder of machine-tools, machinery and metalworking shop equipment.

**Winther Increases Manufacturing Facilities**

KENOSHA, WIS., Sept. 16—The Winther Motor Truck Co., Winthrop Harbor, Ill., which is now at work on its new \$125,000 truck manufacturing plant, is enlarging the scope of the project to some extent by making provision for a one-story building, 50 x 70 ft., to be used for offices and drafting rooms. The factory is expected to be ready for occupancy about the middle of October.

**Oil Co. Effects Another Consolidation**

APPLETON, WIS., Sept. 16—The Badger Producing & Refining Co., which is operating several large oil wells in Oklahoma, has absorbed the Green Bay Oil & Gas Co., Green Bay, Wis., and its holdings in Texas and Oklahoma. This is the second consolidation within a short time, the Badger company having taken over the Appleton Oil & Gas Co. in July. The main offices of the three merged companies will continue to be located in Appleton.

## Current News of Factories

*Notes of New Plants—Old  
Ones Enlarged***New Company Takes Over Fickling Plant**

LONG ISLAND CITY, N. Y., Sept. 16—The Enameling & Stamping Corp. of New York has taken over the plant of the Fickling Enameling Corp., at Second and Webster Avenues, and has re-equipped it with up-to-date appliances designed to handle baked-on enameling, rust-proof coating, etc., on fenders, hoods and automotive accessories of all kinds.

**Velie Develops Kerosene Device**

MOLINE, Sept. 14—The Velie Motors Corp., following a series of tests with a kerosene device for its passenger cars here last Monday, has decided to start manufacturing the device, which it will sell to other makers of cars, the U. S. Government and to Velie owners. The device was first used on Velie tractors. Then it was further developed for trucks, and now it has been further perfected for passenger cars. The tests last Monday were severe. There were present as observers some of the big distributors, and they rode in the cars to note at close range how the device worked.

**Overland Gets British Order**

TOLEDO, Sept. 14—The Willys-Overland Co. has received an order from the British Government for 10,000 semi-chassis for war purposes. The amount of the contract is around \$7,500,000, it is stated, which brings the total business of the company for the United States and its allies up close to the \$50,000,000 mark. It is understood that negotiations for important military work are still pending.

**New Jobber in Utah**

SALT LAKE CITY, Sept. 14—The Motor Mercantile Co. has entered the automotive equipment jobbing trade at 115-117 South West Temple Street in a modern three-story building. It is wholesale only. The principals are: A. D. McMullen, president and general manager, formerly of the Strevell-Paterson Co. and Capital Electric Co.; vice-president, E. J. Raddatz; secretary and treasurer, F. A. Pyke; sales manager, V. A. Culver; buyer, George G. Hansen, formerly buyer for the Chanslor & Lyon Co., San Francisco. The directors are McMullen, Pyke, Raddatz, Culver and J. P. Gardner. The active officers are all well known to the inter-mountain trade.

**Arbenz Factory Practically Suspends Operations**

CHILLICOTHE, OHIO, Sept. 14—The Arbenz Car Co. has practically suspended operations owing to its engineer, N. J. Arbenz, being with the expeditionary force and to the difficulties experienced in obtaining material and labor. A few cars, for which parts are in stock, are being finished.

**Amazon Purchases O'Neill**

AKRON, Sept. 16—The Amazon Rubber Co. has purchased the tire accessory business of the O'Neill Tire & Rubber Co. The purchase includes the exclusive right to the name O'Neill. The O'Neill business will be added to the Amazon business and continued.

**New Plant for Bailey Co.**

CHICAGO, Sept. 16—The George D. Bailey Co., which manufactures the Bailey ball thrust bearing for Fords and Chevrolets, and also the R C magneto coupling, has moved into its new plant at 4500-06 Ravenswood Avenue.

**Moon to Build Army Trucks**

ST. LOUIS, Sept. 16—The Moon Motor Car Co. has contracted to build 300 motor trucks for the Army, the first truck order this company has received.

**Hamilton Making Tractors**

TORONTO, ONT., Sept. 14—The Hamilton Gear Machine Co., largest machine cut gear manufacturing company in Canada, has entered the tractor field with a machine of its own design—the Straight Line Tractor. It is a three-plow job, conservatively rated at 12-25 hp., and is of the four-wheeled type with large diameter front wheels.

**More Room for G. & J. Tire**

INDIANAPOLIS, Sept. 15—The G. & J. Tire Co., of this city, has awarded a contract for a warehouse to cost \$50,000. The new structure will be two stories high, with brick walls and slow-burning construction. It will have a frontage of 70 ft. and a depth of 170 ft.

**Boone Tire Extends Plant**

CHIPPEWA FALLS, WIS., Sept. 16—The Boone Tire & Rubber Co., Sycamore, Ill., which is putting the finishing touches upon its new and main factory at Chippewa Falls, Wis., announces that George M. Graham has become associated with the plant as works manager. Mr. Graham is a tire and rubber expert with wide foreign and American experience and comes to the concern from Pennsylvania. The beginning of regular production at Chippewa Falls has been greatly delayed by the difficulty in getting delivery of some of the machinery and equipment, but most of this is now on the ground.

# Industrial Review of the Week

## A Summary of Major Developments in Other Fields

### August Output of Steel

#### Ingots Shows Increase

The close relation between steel works output in the United States and the steady pushing forward of American lines in France has been emphasized in the past week. Manufacturers of barbed wire were called to Washington to plan for quickly increasing output, after many weeks of restricted production. The entire capacity, which is 50,000 tons a month, may soon be engaged. Besides American requirements a new call has come for 60,000 tons for Italy and 65,000 tons for Great Britain, and the latter amount may be increased to 90,000 tons.

One Pittsburgh mill, on an urgent order for 80-lb. rails for France received last Wednesday rolled 20,000 tons before the end of the week. There is an entirely unprecedented volume of shell steel orders; sheets are wanted in large quantities for trench shelters and rolling kitchens, and in all ways the needs of the American army have been pressed upon the steel mills, until for one week the incessant call for ship plates has become an undertone.

There has been a week of meetings in New York preparatory to the quarterly price conference in Washington, now set for Sept. 19 instead of the day preceding. Lake Superior iron ore producers, particularly underground miners, have formulated their argument for a second advance. Eastern iron ore companies have come together for the first time and will be represented at the price table. Wire companies have agreed that barbed wire should be advanced \$5 a ton and nails by a like amount. The smaller steel makers who buy their pig iron, and who represent about 10 per cent of the finished material output in important lines, will make a stronger appeal than at any previous conference.

Foundry pig iron producers decided at their meeting last Thursday that their case must be presented separately at Washington and not through the general steel committee. Regional prices are being agitated and the Southern furnace companies are especially insistent.

At Washington, while the cry still goes up for greater production, there is little encouragement to the pleas for higher prices, though some producers, both of pig iron and finished steel, are claiming that in the last quarter of the year their costs will be higher than present prices.

Attempts to bring steel plants under the rulings of the National War Labor Board continue and the situation is tense, not so much from actual differences between the manufacturers and employees as from the efforts from without to raise issues that will bring Government interference.

Chicago at last reports definite announcements of the prices secured by agricultural implement buyers through

Government intervention, including 25 per cent discount on shafting and disk steel at 7.5c. An order for 15,000 tons of rivets is being placed this week for Hog Island. Government absorption of bolt and nut as well as rivet output is more complete.

Jobbers have not been encouraged by the week's developments as to army requirements. Their B4 classification gives less and less promise of stock replacements as the revised schedule of imperative shipments to France keeps mounting.

The price of domestic manganese ore is involved in a conference being held to-day (Wednesday) on the amount of Brazilian ore to be imported in the remaining months of the year. If these imports are reduced, exports to South America must be cut down, as manganese is now simply return cargo for ships that will not be allowed to come back light. If manganese imports from Brazil are reduced, higher prices for domestic ores and for ferromanganese will be urged.

The August output of steel ingots is estimated at 3,498,000 tons for 27 working days against 3,532,600 tons for 26 days in July. Steel works production thus suffered to a greater extent last month than that of pig iron.—*Iron Age*.

#### Texas Co. Report Shows Remarkable Record

NEW YORK, Sept. 16—The gross earnings of the Texas Co. as shown by the company's report show an increase from \$26,391,745 to \$80,260,633 during the years 1915 to 1918, each total being for the fiscal period ending June 30. Net earnings during the same period have increased from \$8,024,692 to \$34,873,402 and the surplus for 1918 is \$14,397,241 as compared with \$3,393,327 for 1915. Profit and loss surplus has risen from \$14,529,301 to \$54,667,429.

#### Chevrolet Motor Co. to Dissolve

NEW YORK, Sept. 17—The directors of the Chevrolet Motor Co. are calling a special stockholders' meeting on Oct. 11, at Wilmington, Del., for the approval of a plan involving the dissolution of the company and a distribution of its assets. The Delaware corporation only will be dissolved under this scheme, the several subsidiaries operating under the name of the Chevrolet Motor Co. being continued as going concerns.

As the Chevrolet assets, with the exception of the company's holdings of General Motors stock, have been absorbed already by the General Motor Corp., it was realized there was no advantage in keeping the corporate name of the Chevrolet Motor Co. alive; hence the decision to dissolve the company and distribute its assets to the stockholders.

### Bituminous 17,000,000

#### Tons Behind Schedule

As was to be expected, the observance of the Labor Day holiday throughout the mining regions cut into the production of both anthracite and bituminous coal during the week ended Sept. 7. Bituminous output totalled 11,249,000 net tons for the week (5½ days), while anthracite shipments for the same period amounted to 1,617,579 net tons.

It should be recorded, however, that the miners at quite a few operations made up for the holiday by working extra time the Saturday preceding, and another fact which should be emphasized is that the percentage of absenteeism the day following the holiday was negligible. Appeals to the miners for more regular working time are undoubtedly having their effect.

Bituminous coal output is now approximately 17,000,000 net tons behind schedule, and production for the rest of the coal year must be maintained at the rate of 2,041,000 net tons a day if the deficit is to be made up. The car supply is now excellent, however, and the bituminous mines have everything in their favor for a drive on greater output. Anthracite production for the coal year to date is estimated at 45,645,597 net tons, which is an increase of 1,084,000 net tons over the same period of last year.

Market conditions present no radical changes. The Fuel Administration has the distribution and allotment of all grades of coal well under control, and a determined effort is being made to supply the Northwest before navigation on the lakes closes for the season. Dealers have many unfilled orders on their books, but the total quantity of coal delivered to domestic consumers to date is far greater than was true at this time last year.—*Coal Age*.

#### Fox Leaves Saxon

DETROIT, Sept. 17—C. L. Fox, assistant sales manager of the Saxon Motor Car Co., will leave next week for Jacksonville, Fla., where he will go into training in the Motor Transport Corps.

#### Two New Strom Bearing Offices

CHICAGO, Sept. 16—The U. S. Ball Bearing Mfg. Co. has opened two new sales offices. A San Francisco office at 434 Rialto Bldg. is in charge of S. C. Kyle. A Detroit office at 1437 Dime Bank Bldg. is in charge of A. deMaringh.

#### Abandon Importers' Salon

NEW YORK, Sept. 16—The Annual Importers' Automobile Salon, which is held at the Hotel Astor in New York and at the Congress in Chicago, has been abandoned. Members of the board of directors voted unanimously not to hold the event.

## China Offers Poor Prospect for Automotive Industry

By Harold B. Wilson

CANTON, CHINA, Aug. 8—It will probably be many years before the automotive industries reach any great prominence in China, especially in the South. Canton is the largest of the southern cities. It has 2,000,000 inhabitants and occupies a space of only about 20 sq. miles. Outside of the Bund, a 2-mile street along the river and about three other very short streets, there is not a roadway in the city wide enough for an automobile to operate.

There is one automobile here, belonging to one of the generals, and when it comes down the Bund, it excites as much attention as a circus parade in Bingville. Where possible cartage is handled on the river and canals. Coolies equipped with bamboo poles and rope take care of the remainder.

Before automobiles can be used roads must be built. At present the only means of passage through the rural districts are paths just wide enough for two people to pass on foot or on horse back. Many places these paths are not wide enough for two people to pass on foot and wooden platforms are built over the rice fields for one to stand on while others pass.

The principal farming here is rice and truck growing. Truck patches are usually very small and all the work is done by hand. Rice fields are small also and since the plowing is done when the ground is under water or at least very wet, tractors are cut out of the question. Water buffaloes are the only power for this work.

The coast towns like Hong Kong and Shanghai have many automobiles but comparatively few trucks. Gasoline is so dear and coolies so cheap is the chief reason for this absence of trucks. Automobiles are used mostly for business purposes. These cities are trade centers and as the street car systems are very poor many business men find cars very convenient but expensive, as gasoline costs

approximately \$1 gold per gallon at the present time. The radius of the travel out of Hong Kong is too short for automobiles to be used, to any great extent, for pleasure.

In Canton and Hong Kong the motorboat is far more important than the automobile at present and will continue to be for some years to come. They are really a necessity to business concerns. The Standard Oil Co. and the Asiatic Petroleum Co. have a number of motor houseboats for work in the interior. Other concerns will doubtless follow their example when their business up country has reached sufficient volume to warrant it. The most popular fuel for motorboats is kerosene as the cost is a little less than half that of gasoline. Many of the larger boats are equipped with surface ignition crude oil engines. One Chinese concern, the Hip Tung Wo Engine Co., is doing a thriving business building and operating surface ignition oil engine passenger boats and tugs. The day will come when China will have roads and her people will have money to buy automobiles. First she must have a stable and efficient government and a large foreign trade. She has been marking time for a great many years but is beginning to show signs of progress. Her people are too intelligent and industrious to allow her to always remain in a rut.

### Consolidated Machine Co. Moves

The Consolidated Machine Co., Detroit, manufacturers of screw machine products, tools and gear blanks, has moved to 121 State Street, where more than double the former space is available. C. F. Richards is president of the company and Wayne C. Plummer is secretary and treasurer.

### Blackburn Co. Changes Name

CLEVELAND, Sept. 16—The automobile department of the Blackburn Specialty Co. will hereafter operate under the name of the Cox Mfg. Co. The company will continue the manufacture of locking devices and other accessories.

## From New York to Chicago by Airplane in One Day

NEW YORK, Sept. 14—The landing of the postal airplane at New York, Sept. 10, recorded the first trip ever made by an airplane from Chicago to New York in a single day. The numerous attempts heretofore to make this flight have encountered interruptions which have prevented the completion of the trip until the succeeding day.

Pilot E. V. Gardner, accompanied by Edward Radle, mechanic, left Chicago at 6.25 a. m. in a plane propelled by a Liberty engine and landed at Hicksville, L. I., at 8.20 p. m. Allowing for one hour's difference in time and for stops made for replenishing of gas and oil, the trip from Chicago was made in 12 hr. and 55 min. The actual flying time, however was 10 hr. and 5 min., there being a delay of 1 hr. and 57 min. at Cleveland and another 53 min. at Lockhaven, Pa., in procuring gas and oil.

### Fliers Slightly Injured

Mr. Gardner began his flight at Chicago in a driving rain and encountered a severe head wind at Cleveland. He flew over New York at an elevation of 7000 ft. and landed in the dark on a very bad field at Hicksville, L. I. In taking the landing the machine made a spill, slightly injuring the occupants. Mr. Gardner received a cut on his nose and near his left eye, and Mr. Radle was cut on the arm.

Two bags of mail for New York and connections were carried on the plane from Chicago and delivered at the New York post office.

### McCarthy Drill & Tool Has New Plant

TOLEDO, Sept. 16—The McCarthy Drill & Tool Corp. is now occupying its new two-story factory building at Clinton Street and Oakwood Avenue. About a year ago the McCarthy corporation purchased the Toledo Machine & Tool Co. Since taking possession, the company has expanded and enlarged its business and is handling export orders for drills, reamers and cutters, as well as an extensive direct government business.

# Calendar

### ENGINEERING

Nov. 14-15 New York. Society of Naval Architects and Marine Engineers. Twenty-sixth general meeting. Engineering Societies Bldg., 29 West 39th Street.

### ASSOCIATIONS

Sept. 19-21—Syracuse, N. Y. Semi-annual meeting of the American Gear Manufacturers' Association.

Oct. 7-12—Milwaukee. American Foundrymen's Assn. and allied organizations. Milwaukee Auditorium.

### SHOWS

Sept. 8-20—Greely, Weld Co., Colo. Tractor Show, Central Community Fair.

Sept. 9-14—Milwaukee, Milwaukee Automobile Dealers, Inc. Fourth Annual Wisconsin State Fair. Hart J. Ruddle, Mgr.

Sept. 9-14—Syracuse, N. Y. Tractor demonstration (State Fair). J. Dan Ackerman, Secy.

Sept. 9-15—Madison, Wis. Tractor demonstration (State Fair). O. E. Remy, State Fair Secretary.

Sept. 12-13—Marion, O. Tractor demonstrations, Farm Bureau Associations. M. C. Thomas, County Agricultural Agent.

Sept. 14-21—Chicago. Automotive and Accessories War Exposition. Municipal Pier.

Sept. 19-21—Harrisburg, Pa. Tractor demonstrations, State Fair.

Sept. 23-28—Boise, Ida. Tractor demonstration (State Fair). J. C. Wooley, Moscow, Ida.

Oct. 1-5—Washington, Ga. (Wilkes Co.). Tractor demonstrations, State Fair.

Oct. 12-19—Atlanta. Tractor demonstrations Eastern State Fair and Automotive Exhibition.

Oct. 14-27—Dallas, Tex., Seventh Annual Texas Automobile Show. Texas State Fair.

Sept. 17-20—Riverhead, L. I. Tractor demonstration (County Fair). Harry Lee, Secy.

Sept. 30-Oct. 4—Trenton, N. J. Tractor demonstration (Trenton Fair). Harry B. Salter, Supt.

Oct. 16-18—Ottawa, Ont., International Plowing Match. Tractor and Farm Machinery Demonstration. Experimental Farm.

Oct. 30-Nov. 4—Shreveport, La. Tractor demonstration. State Fair.

Nov. 11-16—Phoenix, Ariz. Tractor demonstration, State Fair.

### RACING

Sept. 21—Sheepshead Bay.

Oct. 5—Cincinnati. Cincinnati Speedway.

SEP 30 1918

UNIV. OF MICH.

"The arrival of Maxwell Truck at Columbus Circle, New York City, after its record breaking run from San Francisco. The entire trip was completed without a single plug adjustment, replacement or attention of any kind, in fact the plugs were not removed from the motor from start to finish."

Ray McNamara,  
Road Engineer.

## Champion

Dependable Spark Plugs

### Dependability Again Shown Over 31 Mountain Ranges

Champion Maxwell, 7½-18  
Price, \$1.00

**T**HE irrefutable evidence of the dependability of Champion Spark Plugs continues to mount higher and higher.

Concerning the remarkable cross-continent run of the Champion equipped Maxwell Truck (3,428.7 miles in 17 days, 8 hours and 20 minutes) Ray McNamara, Road Engineer, says:

"It was not necessary to remove a spark plug from the motor from start to finish, which performance is very phenomenal when the 31 mountain ranges that are crossed are taken into consideration; these ranges vary from two to twelve miles of steady climbing, and the same distance prevails going down on the other side of the mountains.

where it is necessary to use the motor to help hold back the load on the steep grades."

An overwhelming majority of all American motors are equipped with Champion Spark Plugs, because every test and experience demonstrates again and again their superior efficiency and durability.

Champion Spark Plug Company, Toledo, Ohio

## Sell Radiator Insurance

THE only way a motorist can be positively sure that his radiator won't freeze up is to use a non-evaporating, anti-freeze preparation. He can never be sure of alcohol or any other product which evaporates with the water. Besides, the price of alcohol makes it practically prohibitive for the coming winter.

# JOHNSON'S FREEZE-PROOF

This is a logical anti-freeze preparation to stock—it is put up in compact form so will not require much space—there is no freight to pay on the water—it is absolutely guaranteed if used according to the simple directions on the label—it will be the most extensively advertised anti-freeze preparation on the market—it is backed by an advertising appropriation of \$150,000.00 which will be spent in the leading magazines, weeklies and on the billboards.

S. C. JOHNSON & SON Dept. A RACINE, WIS.

I am interested in handling Johnson's Freeze-Proof for the coming winter. Please send me your booklet of Facts about Freeze-Proof—also quotations.

NAME .....  
ADDRESS .....  
CITY and STATE.....  
MY JOBBER IS.....

### Five Year Prestige

We have under observation car in which Johnson's Freeze-Proof has been used for the past five years with satisfactory results. There is no question about the merit and selling possibilities of this popular winter product. Johnson's Freeze-Proof is put up in packages containing 6½ lbs. net, packed twelve to a case. List price \$1.50 each, subject to liberal discount. Use attached coupon for complete information.

## Gear Makers Decide on Closer Co-operation

Comprehensive Standardization Plan Involving All Types of  
Gears Started—Increasing Production and Man-  
Power Conservation the Great Issues

By P. M. Heldt

**S**YRACUSE N. Y., Sept. 21—Getting their complete organizations co-operating to the highest efficiency under war conditions, and complete co-operation with the Government in its war activities, constituted the keynote of the semi-annual convention of the American Gear Manufacturers' Association, which was concluded here to-day.

Not an address was made during the 3 days of the meeting that did not contain some reference to war conditions and ways of meeting them, and a spirit of patriotic fervor pervaded many of the speeches made at the social gatherings.

A representative of the War Industries Board, Charles A. Otis of Cleveland, chief of the Resources and Conversion Section, came to Syracuse to talk regarding plans adopted for the conversion of plants and equipment engaged in non-essential industries to suit them for essential work.

Some conception as to how the members of the association can co-operate with the Government was given by President F. W. Sinram, when he told of the endless ramifications of the use of gears. There are gears in every ship, every airplane, every submarine, every truck, every military tractor, every farm tractor, every motorcycle, every steam shovel,

crane, gasoline locomotive, trench engine, gun, gun-mounts, and gears are in use in all mines, mills, and much electrical equipment. At present 80 per cent of all gear work is war work.

This broad use of gears going into industries very often not closely related and not having common interests points to the great necessity for standardizing in order that production be kept at its highest percentage and man-power be conserved as much as possible.

President Sinram emphasized the fact that few gears are purchased directly by the Government, yet gears invariably form parts of all complete war machines in use.

"The requirements of the nation," said President Sinram, "predominate over every other consideration. It devolves upon every gear producer to apply his plant and equipment where it will fit into the general requirements to the best advantage. Production is the need of the hour. Co-operation between those operating in the same field is demanded by the present. This has become a patriotic duty and is not only encouraged, but expected by the Government.

"We live in a new era. Standardization is not

only encouraged and recommended by the Government, but the latter has seen fit to command it in certain industries in the interest of conservation, production and economy. Our program for technical standardization is gradually taking shape. It should receive considerable impetus during this meeting. Let all concerned keep ever at it during the ensuing 6 months in order that the current association year may record material progress. Standardization is important to the future of the industry.

"Another phase of standardization—commercial—is receiving consideration; uniformity of practice is desirable in many connections. The sessions of this meeting may open the way for a step forward in this direction.

"Perhaps a few statements of facts pertinent to gear production may suggest what is necessary from the different angles for satisfactory performance on the part of the industry.

#### The Importance of Gears

"1—There is no finished product more vital to the war than gears.

"2—The production of gears is a technical, highly specialized business. Efficiently conducted it demands in personnel ability—commercial, technical and mechanical—of a high order.

"3—Many phases of gear production demand skilled workers to an extent not required by the average metal working industry.

"4—A large fixed investment—plant, machinery and tools—is required for any considerable scope and volume.

"The requirements of the nation are paramount to every other consideration. It devolves upon every gear producer to apply his plant and equipment where it will fit into the general requirements to the best advantage. Production is the need of the hour.

"Co-operation, as never before, between those operating in the same field is demanded by the present. This has become a patriotic duty and is not only encouraged, but expected by the Government.

"We live in a new era. Standardization is not only encouraged and recommended by the Government, but it has seen fit to command it in certain industries in the interest of conservation, production and economy.

"Another phase of standardization—commercial—is receiving consideration; uniformity of practice is desirable in many connections. The sessions of this meeting may open the way for a step forward in this direction.

"Summer is over. Our meeting here to-day marks the opening of the fall and winter season. It is also expected to represent the start to renewed activity in every phase of association endeavor."

#### How Gear Makers Can Co-operate

The most tangible way in which the gear makers can co-operate with the government, by increasing production and conserving man-power, is along the lines of standardization, and a complete program for pushing standardization work was outlined and an organization of committees to carry this work out arranged for. This was followed up by instructions to all the committees on the work to follow in this field. B. F. Waterman, chairman of the General Standardization Committee, has this work in charge, and his program has in mind considering the design of gears so as to evolve rules and formulas which will make it possible for all of the forty-seven members of the gear association to manufacture approximately the same product.

This program, outlined in detail later, arranges for the consideration of the design of all types of gears, so that different makers can produce approximately the same design; and it also involves a standard specification sheet for use in contracts and orders.

Still another example of how the members of the association may co-operate as a war conservation measure was suggested by Frank Burgess of Boston, when he reported on

the possibility of one maker loaning hobs to other companies. At present there are over 1800 hobs owned by the members and scarcely more than one-third of these are in constant use. By the loan suggestion it would be possible to keep in use a much greater percentage of the time.

The association appointed a War Service Committee, and it is expected will be a fit method of association representation on matters with the government.

The increasing use of women in gear factories and the efficiency of these was one factor of the meeting. W. Diefendorf gave a special address on this subject.

The advantages of housing workmen under war conditions was well outlined by C. V. Stuart, who told of the results attained by one of the steel companies in this field.

The report of the membership committee showed that 14 well-known gear concerns had applied for membership in association, and their applications were accepted. The members are the Cullman Wheel Co., Chicago, the Br. Lipe Gear Co., Syracuse, and the Indianapolis Tool & Co., Indianapolis. This brings the number of concerns represented in the association to 47.

B. F. Waterman, chairman of the General Standardization Committee, presented a committee report. Between the V. Sulphur Springs meeting last April and the present meeting the committee held two meetings at which the conclusion reached that certain items in gear design and manufacture were ripe for standardization. Sub-committees have been appointed to deal with the following classes of gears respectively: Bevel, spur, worm and spiral herringbone, position gears and sprockets. There will also be a hardening and heat-treating committee and a committee on gears pinions for electric railways and mines.

Instructions were issued to each committee outlining subjects which it should deal with from the standpoint of standardization, as follows:

#### Recommendations for Standardization

##### To the Bevel Gear Committee

1—We think it well to consider the design of gears with the aid of evolving rules and formulas enabling all members to turn out approximately the same product. As each sub-committee representing a type of gear will work on the subject of design, there should be consistency in all formulas.

2—Formulas for strength of gear teeth and the relation of strength to wear.

3—Adopt a standard long addendum for straight tooth gears and consider a modification of addendum and dedendum agree with the correct or normal pitch as is practiced in herringbone gears.

4—Make up a standard specification sheet for use in contracts and orders.

##### To the Spur Gear Committee

1—We think it well to consider the design of spur gears with the aid of evolving rules and formulas enabling all members to turn out approximately the same product. As each sub-committee representing a type of gear will work on the subject of design, there should be consistency in all formulas.

2—Develop a formula for the strength of spur gear teeth and relation of strength to wear.

3—Make up a standard specification sheet for use in contracts and orders.

##### To the Worm and Spiral Gear Committee

1—Rules for the design of worm gears enabling all members to turn out approximately the same product.

2—Formulas for the strength of worm gears and the relation of strength to wear.

3—A specification sheet for use with contracts and orders whereby customers and maker will know just what will be produced.

##### Committee on Composition Gearing

1—Standard methods of construction advised by manufacturers of this type of gearing.

2—Standard methods of handling the material to prevent absorption of moisture.

3—Strength formulas for various kinds of material used in type of gearing.

4—Best methods of cutting and the speeds and feed permitted.

5—Tabulate successful long-lived drives, giving full details as to full load, intermittent load, speeds, etc.

6—Make up standard specification sheet for use in contracts and orders.

##### Hardening and Heat Treating Committee

1—Depth of case and its relation to pitch and service.

2—Materials and treatments suitable for different services.

3—Standardizing scleroscope and Brinell readings.

*Herringbone Gear Committee*

- 1—Formulas whereby members will produce gears approximately of the same design and where others interested might do so.
- 2—Formulas for strength of herringbone gears and the relation of wear to strength.
- 3—Tabulate successful designs giving details.
- 4—Get up a specification sheet for use with contracts and orders whereby customer and manufacturer will understand just what is to be furnished.

*The Sprocket Committee*

- 1—Evolve formulas for dimensions of hubs, arms and rims, having in mind the design of spur wheels which are now being considered by the spur gear committee.
- 2—Another matter that was brought up was the question of when small sprockets should be hardened. Some standard practice might be determined here by working in conjunction with the chain manufacturers. A table of the strength of various kinds of chains with the safe working speeds would be useful. This data, of course, must be obtained from the chain manufacturers. (A copy of a letter received from the committee on Steel Roller Chains of the American Society of Mechanical Engineers in which they agreed to co-operate was sent to each member of this committee).

*Electric Railway and Mine Committee*

- 1—Evolve rules and formulas whereby all members will turn out approximately the same product. As each sub-committee representing a type of gear will work on the subject of design, there should be consistency in all formulas.
- 2—Develop formulas for the strength of gear teeth and the relation of strength to wear.
- 3—Make up a standard specification sheet for use in contracts and orders.

Each list of subjects was accompanied by the following comment: "In undertaking this work it seems advisable to limit ourselves somewhat in the number of subjects that we consider so that we will have a better chance of concentrating and finishing up the various subjects; it may be that the committee will decide that these be considered in a different order than given or that something else is of more importance, when they will feel free to take it up, although we trust that the sub-committees will keep the General Standardization Committee in touch with what they are doing."

The report of the committee on commercial standardization, which is drawing up specifications which are to accompany all bids and contracts for gears, was not quite ready, but William Ganschow of Chicago, a member of this committee, read an outline of the items to be covered. It is proposed to submit the revised specifications to the membership for comment once more before putting it up for a vote.

*The Hob Exchange Plan*

Frank Burgess of Boston read a preliminary report of the hob exchange committee. The idea is that a tabulation shall be made of all hobs owned by members, with a note as to whether they are willing to loan them to other members under conditions agreed upon. A survey made shows that over 1800 hobs are owned by member companies and that not more than one-third of them is in even fairly constant use. The plan has the hearty approval of several members and is directly in line with the conservation movement.

John B. Foote of Chicago made a comprehensive report for the labor committee. The following war service committee has been appointed to represent the gear industry: F. W. Sinram, chairman; S. L. Nicholson, vice-chairman; Frank Hamlin, secretary; Frank Burgess, H. W. Chapin, James E. Gleason, F. T. Zollinger, T. G. Meachem, E. J. Frost and William Ganschow. The personnel of this committee was approved as being well selected both as regards branches of the gear industry and sections of the country.

On Thursday evening the members and others in attendance were the guests of the Brown-Lipe Gear Co. and the Brown-Lipe-Chapin Co. at a dinner given at the Onondaga. The affair was a very enjoyable one.

During the Friday morning session W. H. Diefendorf of the New Process Gear Corp. read his paper on the employment of women in the gear industry. Mr. Diefendorf said in substance:

"For years back we had observed women employed in the mechanical arts, not only in light and intricate work, such as inspection, watch making, but also operating machines working on fairly heavy and sizable parts, which latter practice, I believe, was carried to a much greater extent abroad. We, therefore, decided to try the experiment in one of our gear cutting departments on some of our lighter work. The re-

sults justified our hopes and we proceeded to extend the system to cover other sections and departments, which enabled us to supply the necessary quota of operatives at a time when they were badly needed.

"Recent visits to plants producing war material revealed the fact that women are now being employed, not only on grinding operations, light lathe work, etc., but also on heavy work, such as the milling of engine bases, as well as on certain portions of engine assembly. Naturally the positioning of heavy parts requires the use of chain hoists and the aid and guidance of male overseers and assistants. In the light of such facts it is apparent that women operatives *can* be used in the heavier as well as the lighter varieties of gear work, though probably the logical field for such help is in connection with the blanking and cutting of small gears on a piece work basis where the operative receives a financial return for her labor commensurate with her application and her natural ability.

"Women also make excellent inspectors, their delicate touch—more sensitive than that of men—aiding them in detecting imperfections when giving the gears a rolling test, and this, coupled with their quick eyes and nimble fingers, gives them an advantage in gaging and visually inspecting finished parts.

"War conditions have, of course, accentuated the seriousness of the labor problem and with the close of hostilities, in all probability, many of the women now employed in the mechanical trades will return to their former status, but it does not seem at all probable that, having become accustomed to a fat pay envelope, they will willingly go back to the less lucrative field of housework, etc. Consequently, so long as there remains a demand for operatives at good wages we may expect to see woman a keen competitor of man and in certain lines running in the forefront of the race, resulting in a condition which, if continued, will undoubtedly force upon the community the consideration of such things as communal homes, communal kitchens, etc.

"To my mind there can be but one reply to the question in hand, which is that the up-to-date gear maker not only can but should accord to woman a place among his operatives."

Mr. Otis, of the War Industries Board spoke for several hours, dwelling upon the great shortage of steel which is due to a shortage of coal that results from lack of sufficient manpower; and he insisted upon the absolute necessity that the steel requirements of the fighting forces be met first.

*The Steel Outlook*

At the final meeting this morning C. E. Stuart of the Central Steel Co., Massillon, Ohio, gave a talk on The Outlook of the Steel Supply. He read a letter from J. L. Replogle in which were given the estimates of steel production and war requirements which have already been published. These, as is known, leave a deficiency of 6,000,000 tons for the current 6 months. Fortunately this is only a "paper" deficiency and various things will tend to lessen the actual consumption for war purposes.

Mr. Stuart also dwelt on the labor situation and described some methods employed by his firm to increase the efficiency of their labor. Working in co-operation with a land company the concern has invested \$112,000 in bunk houses for laborers close to the steel mills. Each contains a cot and bed. The bed is properly made and the house swept out during the day, so that when the tenant arrives in the evening he finds it neat and tidy. Formerly many of the foreigners employed at the mills roomed at a considerable distance outside the city, where, it was found, they were subject to baneful influences. Now, with the men close to the factory, on the addition of the land company, they are under police supervision furnished by the company. A refrigerating plant was installed and each workman is allowed a limit of three bottles of beer a day. The investments thus made have resulted in an appreciable increase in efficiency and the workmen are encouraged to and do buy the houses after they find they like the place.

Another paper read during this session, by C. E. Crofoot, was on "Trade Acceptances." Mr. Crofoot favored the use of trade acceptances in the gear industry and the recommendations made in his paper were referred to the committee on commercial standardization.

# Useful Data From Harrisburg Tests

## Tractor Demonstration, Staged by Department of Agriculture, Gives Valuable Performance Information—Plow on Basis of Advertised Capacity

**H**ARRISBURG, PA., Sept. 24—A commendable effort to stage tractor demonstrations that will furnish useful tractor performance data for such agricultural areas as Pennsylvania was carried out by the Department of Agriculture of this state during the last 4 or 5 days.

The demonstrations were originally scheduled for September 19, 20 and 21, but owing to rain the program was entirely upset and the demonstrations were not completed until tonight. Unfortunately two or three of the contestants had made other arrangements at Pennsylvania county fairs, and they had to withdraw their tractors when the demonstrations were scarcely one-third over.

These state demonstrations were not spectacular; only fifteen different models of tractors competed, but they were epoch-making in that a close record was kept on all of the work done. Machines were given approximately 2 continuous days at plowing, followed by a fraction of a day on fitting the soil for winter wheat, and seeding.

### Observer on Each Tractor

During every stage of the demonstration each tractor was accompanied by an official observer who recorded the exact time required for the particular work; the number of stops made, and the length of each, and information as to whether these were due to troubles with the tractor, or with the plow, or other equipment; they also reported the exact amount of fuel consumed by each tractor in each of the jobs to which it was assigned.

All of this information is not as yet available but will be given out by the Department of Agriculture in the next week or 10 days. One report has been given out to date which covers a 3-hr. period of plowing on typical Pennsylvania land. This report, published herewith, contains much valuable information on the performance of the tractors, particularly on smaller areas than that plowed at the national demonstrations.

The plowing was done in a 42-acre field measuring approximately 76 x 90 rods; the furrows were 76 rods in length. Two-thirds of the ground was clean sod, and the one-third an old corn stubble in which the weeds were 3 ft. in height. All of this ground was very hard until 2 days previous to the demonstrations when it was brought into good plowing condition by the heavy rains.

### Accurate Information Sought

One of the purposes of the Pennsylvania Department of Agriculture in staging these demonstrations was to secure an accurate line of information on what different tractors would do under Pennsylvania conditions. The Pennsylvania farmer does not question what a tractor will do on the prairie stretches of Kansas, but he has the Missouri instinct with regard to what it will do on the hills and among the stones of his own state. The Pennsylvania farmer also has some peculiar ideas as to how farming must be done in his locality and he is doing his best to discover the capacity of the tractor to meet his local requirements.

He also feels that the rate of plowing which is possible in the western states is not possible in Pennsylvania. He is further of the opinion that fuel consumption in his state is higher than that in the West.

The 3 hr. of plowing, which is covered by the report herewith, is not a complete answer to this question, and several more demonstrations of this nature will be required before accurate figures are obtained. For example, in the field plowed there were no stones, although in the fields not covered by this report, much time was lost by stones. The field covered in the present portion of the report is practically level

and so gives no clue as to the performance of tractors on hilly ground. Hilly conditions were encountered but the report on them is not ready.

### Test Based on Advertised Capacity

The tabulation herewith is based on each tractor plowing in a 3-hr. period the amount it is supposed to plow according to the advertising of the manufacturer. In laying out the plot for each tractor, the area allotted was based on the speed of the tractor in m.p.h., the number of plows, and the width of the plows.

A definite area was staked out for each tractor and this is given in the fifth column of the tabulation, which is headed, "acres plowed." The assumption was that all of the tractors should plow their respective area in 3 hr. flat, providing they averaged the speed given in the entry blank. This had to include all of the time consumed in turning at either end of the field.

As to how close the different contestants came to this schedule is shown by the fourth column from the end headed "gross time." The figures are given in hours and minutes. This gross time includes time lost for stops due to the tractor and also the plows as given in the last two columns. From this it will be seen that only one tractor finished ahead of its 3 hr. schedule. This was the Frick, which was 8 min. ahead of schedule. This tractor in doing its plowing had lost 2 min., 1 min. for tractor stop and 1 min. for a plow stop.

### Many Closely Approached Time Limit.

There were several other tractors that approached closely to their plowing schedule, or as in this case, nearly finished their plot within the 3-hr. period. The Parrett was 5 min. over its schedule. This machine had to plow in the corn stubble which was knee high with weeds and if the recorded plow stop were eliminated, its net plowing time was only 2.5 min. above the 3-hr. schedule.

The new International four-cylinder tractor, using a vertical engine—this tractor has not been seen in western demonstrations—had to operate through the same weeds that the Parrett did, and it finished 5 min. ahead of its schedule, or in 2 hr. and 55 min. It lost 6 min., due to plow stops, so that its real net plowing time was 2 hr. and 42 min. or approximately 17 min. under its entered speed. It entered at 2.5 m.p.h. speed and performed at 2.54 m.p.h.

There were other tractors that came close to finishing on the 3-hr. schedule. The Case 9-18 model finished in 16 min. over the 3 hr. The International Harvester Titan model was only 8 min. over the 3 hr., and if a 4-min. plow stop is deducted its net plowing time was but 4 min. over the 3 hr.

The Waterloo Boy finished in 3 hr. and 13 min., or 13 min. above schedule. Allis-Chalmers finished 13 min. above schedule. The Huber was 23 min. above schedule.

### Real Reason for Delays

There were very legitimate reasons why some of the tractors could not plow on schedule. In this connection the work of the Cleveland must be noted. It was the lot of this tractor to draw a very bad section of land, part of which was made up of a rough fence bottom extending from one end to another of its area. The fence had only been removed the day previous and it was almost impossible to keep the plows clean during several rounds while this was being plowed. Over two-thirds of the ground the Cleveland had to plow was overgrown with weeds, which delayed the work. This tractor was entered to plow at 3.5 m.p.h. and its actual speed worked out at 2.54.

There were some of the other tractors which did not per-

form up to their rated speed for different reasons. In some cases the machines were fresh from the factory and were not sufficiently worn in to put up the supreme test.

In the tabulation the tractors that had to plow on the corn stubble overgrown with weeds were the Emerson-Brantingham, Knickerbocker, Parrett, I. H. C. and Cleveland. The Reed tractor withdrew after making a round or two due to clutch troubles.

The Knickerbocker is a Ford attachment in which a special rear axle with heavy wheels is fitted to a touring car body. It had a severe test, as its entire plowing area was in the weedy section.

The Emerson-Brantingham was the only tractor to haul four plows.

#### Fuel Consumption Figures Valuable

The fuel consumption figures, while accurate and valuable, are perhaps not sufficiently comprehensive to be taken as a Pennsylvania criterion. They are, however, the best figures available, and give a pretty good indication of what can be expected. With those tractors using kerosene the consumption per acre is over 3 gal., with the exception of two machines, namely, the Emerson-Brantingham, which pulled four plows, and the Frick, which pulled three plows.

These fuel consumption figures were quite amazing to many of the contestants, who imagined they would not use so much kerosene. One grade of kerosene was used, which was the standard grade sold in Pennsylvania. All tanks were filled from the same tank wagon. These fuel figures do not include the gasoline used for starting. In some cases a good deal more gasoline was used than was required for starting.

For example, the Emerson-Brantingham used over 4 gal. of gasoline, or very close to a gallon per acre, in addition to its kerosene, so that its low kerosene consumption figure must only be read in connection with the gasoline used as well. This does not apply to the Frick, which used a very small quantity of gasoline, approximately 1 pt.

There were three tractors that used gasoline entirely. These were the Cleveland and the Moline, both of which pulled two-bottom 14-in. plows, and were entered at a speed of 3.5 m.p.h. The Moline did its plowing in sod, whereas the Cleveland had the corn stubble and the rough fence bottom. The fuel consumption of these two was remarkably close, Moline averaging 3.18 gal. per acre and Cleveland 3.21. Had both been working on the same class of soil, it is questionable which would have shown the better performance. The net plowing time of the Cleveland was 3 hr. and 47 min. and that of the Moline 3 hr. and 55 min.

Generally speaking, the fuel consumption for those tractors using gasoline was under that of those using kerosene, the Frick being the single exception. The average of gasoline per acre was pretty close to  $\frac{1}{2}$  gal. less than that of the average of kerosene.

There were remarkably few stops due to tractor troubles, the Reed being the only serious case. The Knickerbocker or Ford had 45 min. checked against it for tractor stops, much

of which was due to repairing the fan belt. The majority of the other tractor stops were due to changing spark plugs, tightening terminals, repairing fan belts, and adding water to the radiator.

Although no official record was kept of the oil consumed, all of the tractors filled up before starting, and one or two were compelled to add oil to the engine before the 3 hr. were up. The rules had contemplated keeping a record of the oil but it was wisely decided not to do this. When many of the tractors drew off the crankcase oil at the end of the period it was badly thinned, undoubtedly due to kerosene getting past the pistons into the case.

In connection with the consumption of oil in a tractor engine, it would seem best to make a distillation test of the lubricant in the crankcase after the test to show the percentage of kerosene. This has been done with motor trucks and valuable results have followed. It would appear to be the only accurate means of ascertaining how successfully the kerosene fuel has been burned. Such distillation tests would furnish valuable information for the tractor industry.

The rules and regulations governing the demonstrations were very simple. It was required that each tractor should, as stated, plow at its rated speed, and do this at a depth of 6 in. The different entrants drew for positions on the field. After the day's work was done the tractors were packed under military guard.

The Pennsylvania Department of Agriculture selected as observers what are known as county agents. These are generally college graduates, resident in the different counties, and employed by the state to give advice in the county on all questions relating to agriculture. Many of these county agents have staged the conventional 1-acre plowing demonstration during the past few months, and many others are planning to have similar demonstrations next spring.

#### State Purchased 35 Tractors

The State of Pennsylvania, through the Department of Agriculture, purchased last spring thirty-five tractors of different makes, and has been operating these in different sections of the state. The Department of Agriculture has daily reports on the work of these and it is largely because of this that the present demonstrations were decided upon.

It is expected next week to publish reports showing the fuel consumption for plowing on hilly soil containing some stones, and other reports showing the fuel consumption required in fitting the ground for winter wheat and seeding it.

Many of the county agents who acted as observers are of the opinion that if tractor demonstrations in Pennsylvania are to carry real conviction to the farmer, they must plow and cultivate as is considered best. There are those who are asking for plowing 8 to 10 in. deep and turning a furrow 10 or 12 in. wide instead of 14 in. They claim that you cannot do proper plowing with a 14-in. furrow unless the depth is more than 6 in., as called for in the present demonstrations. The 6-in. depth is satisfactory for winter wheat, but is not satisfactory for spring plowing.

# Purchasing Agents Discuss Priority

Representative of War Industries Board Explains Its Desire to Be Helpful—Over 400 Attend Banquet

**D**ETROIT, Sept. 23.—(Special to AUTOMOTIVE INDUSTRIES).—Five hundred purchasing agents from all lines of industries gathered at the Pontchartrain this morning to attend the opening session of the annual convention of the National Association of Purchasing Agents. With a gathering representing several billion dollars' worth of purchasing power annually, the convention is one of the most significant gatherings yet held by this rapidly growing association.

Registered delegates represented the biggest manufacturing concerns from Connecticut, California, Michigan, Illinois, Indiana, Missouri, the Atlantic Coast, centering at New York; western New York State, Ohio, Pennsylvania, and other sections of the country.

There were eighteen delegates from Philadelphia, seven from Springfield, Mass.; seventeen from Connecticut, eleven from Rochester, four from Dayton, twelve from Toledo, six from St. Louis, six from Milwaukee, twenty-two from Buffalo, thirty-six from New York, twenty-five from Pittsburgh, seven from Columbus, seventy-three from Detroit, fifty from Cleveland, thirty-nine from Chicago, seven from central Indiana and the remainder from miscellaneous sections of the country as far west as the Pacific Coast.

## More Than 400 In Attendance

More than four hundred members attended the annual banquet, Sept. 24, an event which is felt by the members to mark another great forward stride in the growth of this young but powerful organization. A strong address by Albert C. Ritchie, Counsel for the War Industries Board, who told the real meaning of priorities, and the causes back of the work of the board, was one of the important features.

Our raw materials are plentiful but not inexhaustible, Albert C. Ritchie, who is attorney general of Maryland as well as counsel for the War Industries Board, told the members of the association. Mr. Ritchie represented the War Industries Board and was assigned to deliver a message from the Board by Chairman Bernard M. Baruch.

Steel unfortunately happens to be the material which is shorter than others, yet in addition to being needed in the war it is needed in practically all industries. Our resources must be first for war and then for industry, and it is part of the work of the War Industries Board, as defined by Mr. Ritchie, to see that the various divisions of war work secure the proper amounts of raw materials in the correct relative quantities and then to see that the industries get the material in the quantities in accordance with the war program of the government.

Our allies are calling upon us heavily and we must support them because their work is the same as ours. For this reason the War Industries Board must make a study of the material situation in every particular and first see what the requirements for war are, and then apportion what remains to the industries.

The Board has at work approximately 1500 men, all directed by the seven members of the Board who are the division leaders. These men have made amazing savings by cutting down the number of different models or styles of product in practically every line of industry. They have entered shops and suggested better methods of production and have gone to factories in work not useful to winning the war and turned them over to war work.

ALBERT C. RITCHIE  
*Attorney-General of Maryland and  
Counsel to War Industries Board*

Mr. Ritchie cited building materials as a typical example. He said that the total amount of steel manufactured in the United States during the past six months was 17,000,000 tons, while the war program called for 21,000,000 tons. The steel is also needed for bridges, buildings, rails and any of a great number of industrial purposes. For this reason the work of the Priorities Committee on this subject alone presents problems of greatest delicacy.

Talking of priority, Mr. Ritchie said it is not only necessary to determine if the firm is making war material alone. The degree of importance of these war materials must be properly graded so that they will arrive in the proper sequence. Of the steel available, General Pershing demands enough for railroads to support the advance of the armies. Mr. Schwab wanted the steel for ships in order to keep the line of communication across the ocean unbroken. Mr. McAdoo demands the steel for rails and locomotives on this side of the water because the lines of communication begin here.

## How Priority Applies

It is the duty of the manufacturer, according to the War Industries Board, to give precedence in manufacture to orders which carry the highest priority rating, so that these ratings apply not only to transportation of materials but also to their course through production.

The War Industries Board is, of course, concerned with many matters outside of priority. There is also the work of price fixing and conservation. The industries have welcomed the efforts of the Board in both these directions and called the Board in to help them in their problems. The number of buggy models, for example, has been cut down to two instead of hundreds which previously existed. The number of automobile tire sizes is being reduced to nine. Another great division, headed by Mr. Otis, studies plants and their equipment for the purpose of changing them over to war work if they are not engaged in some essential industry.

Mr. Ritchie recommended that all those concerned in any way with priority problems write to the Board for publications which are now printed on the subject. The inquiries should be addressed to the secretary of the Board, and these

William Gugenheim,  
Bauer Bros. Co., Springfield, Ohio

W. P. Ogden

Herbert E. Cass,  
Merrett Soule Co., Syracuse

booklets will clear up many of the questions which are now being asked regarding the manner of handling priorities.

Above all, the speaker explained, the Board is not so much a regulating body as a co-operative one, and it wants the people who are working with these problems to send their men to Washington to get in touch with the divisional heads of the Board to discuss their problems.

Priorities was the subject principally under discussion at the Tuesday meeting. That purchasing agents are greatly puzzled regarding the handling of priorities was evident.

A committee was appointed to draw up a resolution that the sub-contractor be allowed to have the same priority classification as the first contractor. This action is sufficient to show how little informed buyers really are regarding the manner of using priorities, because it has frequently been pointed out in Washington that the sub-contractor has the same status as the main contractor in priority.

W. H. Ogden of the Scovill Mfg. Co., Waterbury, voiced the sense of the meeting when he stated that the Government is screwing the lid down tighter and tighter and everyone must arrange their business so that they are helping the cause.

Another member stated that the committees appointed by bodies such as the Purchasing Agents' Association can do no good, since they cannot add anything to the work that the Priorities Board is already accomplishing.

"We must remember," this member said, "that we are in this war and have to win it, and all our buying business should be conducted with that idea uppermost."

So that manufacturers and the War Industries Board can come to a better understanding President E. L. McGrew, purchasing agent of the Standard Underground Cable Co., Philadelphia, appointed a committee consisting of D. E. Ferguson of Pittsburgh, chairman; Thomas F. Kenney of New York, Charles A. Steele, Philadelphia; V. W. Bergenthal, St. Louis, and W. E. Hopton, Syracuse.

Some of the papers read included "Commercial Bribery," by W. P. Ogden, Scovill Mfg. Co., Waterbury; "Should the Stores Department Be Under the Purchasing Agent's Control?" by William Gugenheim, Bauer Bros. Co., Springfield, Ohio; "Buying Substitutes," by E. J. Solon, Owens Bottle Mach. Co., Toledo, Ohio.

The program included James Schermerhorn, Detroit *Times*, a nationally-known figure, toastmaster; Edgar A. Guest, whose war poems are widely known, and Dr. M. S. Rice, a powerful patriotic speaker who made a strong appeal to every man and woman in the country to make every sacrifice and to throw themselves heart and soul into this conflict to make war head the final list of non-essentials.

In addition to the business program, the visitors were conducted to the plant of Henry Ford & Son, tractor manufacturers, at Dearborn, and the Burroughs Adding Machine Co.

## How Purchasing Agents May Serve the Nation in Their Work

By C. A. Woodroof  
Saxon Motor Car Co.

THE purchasing agent can best serve the nation in his work by practicing the principles of conservation, co-ordination and co-operation. It is only by the help of our fellow men that we accomplish anything. A man alone can do little of significance, but with the help of others he can build railroads and houses, and his power is practically unlimited.

It is only necessary to look at Russia, which, through its scattered efforts and lack of unity of purpose, has become nothing more or less than a gigantic jig-saw puzzle. Contrast this with England, France or the United States, where the united efforts of the people have succeeded in accomplishing a great purpose, and who on this account are going to put a glorious end to this war.

The purchasing agent is in a position to study conditions and to apply the results of his study to his work. He knows the fundamentals of a great many industries which center

in his product. The purchasing agent of an automobile factory not only knows the intricacies of his own business, but he must also have a knowledge of every other line, whether it is the manufacture of a cotter pin or of photography from the clouds which cover his plant.

He must know the location of every plant making the product in which he is interested. He must know the course of making this product; he must know the equipment of the plant, and its capacity, in order to conduct his purchases with the greatest amount of intelligence.

As a result of his specialized knowledge, great numbers of the members of the Purchasing Agents' Association have been called to Washington as commissioned officers or civilians to aid the Government in the co-ordination of their war orders. Purchasing agents can help each other.

There is nothing like personal experience, but second to

F. J. Salom,  
Amens-Battle Co., Toledo

Frank T. Lodge,  
Detroit

E. L. McGrew,  
Standard Underground Cable Co., N

this is the personal experience of others, and if we can through this association permit each other to profit by our personal experiences, one of the greatest aims of the organization will have been accomplished.

The war will impose on us a high tax for a long time. It is only by conservation and thrift that we will meet this tax. It has not been necessary hitherto for us to practice this strict economy, but it is now necessary. A lesson is pointed out to us by the French. After the Franco-Prussian war such a heavy indemnity was imposed on France that Germany thought that she would never again be able to oppose the scheme of German world dominion. It was the stocking of the French peasant which saved France.

The standardization of catalogs is a step in the right direction. The use of two colors and a standard size of sheet will conserve ink and paper. It will help the paper manufacturer, the envelope maker, and if the loose-leaf style of catalog is decided upon, it will eliminate the mailing of thousands of sheets of unnecessary matter to people who are not interested in it. It will conserve the efforts of postal clerks and of the thousands of people through whose hands the extra matter would have to pass.

The purchasing agent should only order what material he actually needs. Under no circumstances should material be hoarded. The purchasing agent should go directly to his source of supply, ordering exactly what he needs and conserving freight space on the shipment of this material. He should by no means extend his inquiries broadcast, creating a false demand and an impression of shortage where none such really exists.

The purchasing agents can suggest that automobiles be used in place of railroad trains. The truck can supplant the pinch bar and freight car for short distance moving. He can utilize the knowledge gained in his visits to other plants to suggest better and more efficient methods in his own.

He can study the economical use of materials, as, for instance, in reducing the tin content in babbitt in order to furnish a greater supply for Government needs, and, furthermore, he can use over any obsolete stock which other purchasing agents have on hand, thus helping all parties.

Above all, the purchasing agent should not compete with the Government in buying. The biggest thing a purchasing agent can do now is to aid the Government by honestly observing priorities and buying efficiently. In purchasing, it is disloyalty and treason to compete with Uncle Sam now.

## A New Book on Austin Buildings

THE "Austin Book of Buildings," No. 5, just off the press, is a 64-page volume completely covering the service performed to-day by the Austin Co. of Cleveland.

Starting with a description of the Austin method, which is an application to the construction of industrial buildings

of the principles of quantity production by the development of standardized parts and models interchangeable in a manner as to provide a large array of buildings both in and size. The method is largely used to-day because of the fact that it provides for the erection of substantial fire buildings in a minimum time.

There are chapters covering the 10 Austin standardizing units, combinations of Austin standards, specifying the Austin industrial building service, equipment and service.

There are a large number of illustrations showing buildings that have been erected at short notice for large industrial undertakings. Detailed drawings and cross section floor plans, side elevations and front elevations are given.

## Teaching by Intensive Methods

IT was at first believed that a man or woman wholly familiar with machine shop practice could not quickly be trained for operations of the greatest precision in repetitional production, but the contrary is the fact. H. E. Miles, chairman of the Section in Industrial Training of the Council of National Defense, in a recent interview said: "A new person, mechanically inclined and of good intelligence, can be taught a single machine (lathe, grinder, miller, in surprisingly short time under highly specialized instruction."

At first, if the machine is complicated, it must be a challenge for the operator, but shortly he or she will set up the machine for any one of a series of similar operations. This has been carried to unbelievable extent in England, and in the United States women in about three weeks have been taught to run single machines within limits of one-thousandth to sometimes five ten-thousandths of an inch.

Many of the leading machine tool builders in Cincinnati, Worcester and elsewhere are developing this type of worker satisfactorily.

## Removing Temper From Steel

THE Swiss journal, *Die Elektroindustrie*, gives particulars of a process for removing the temper from hardened steel. The piece to be softened is placed on a bed of iron at red heat and covered by a plate of cold iron. The whole has cooled the piece of steel, whatever its previous quality and degree of hardness, is detempered completely, and can easily be worked without its quality having undergone any change by, for example, decarburization. The method is specially applicable to the unhardening of more particularly punches and dies. Tests have given excellent results, and the method has the advantage that all pieces of steel do not show any shrinkage after treatment.

# Hawaii Has More Automobiles Than China and Japan Together

## Truck and Tractor Possibilities—Used Car Problem Very Much Present—Analysis of Selling Field

**T**HE Hawaiian Islands constitute a better export market than China and Japan, and in these islands there are to-day more automobiles than in China and Japan combined. At the end of 1917 there were 2087 cars in the islands as compared with 1678 at the end of the previous year, 1381 at the end of 1915 and 939 at the end of 1914, or 6 months after the war started.

Tom O. Jones, for years connected with the automobile industry, gives these figures in a recent report he has made to the Department of Commerce as a result of a special investigation be made for the department throughout Japan and in parts of China and in the Hawaiian Islands.

According to the report of Mr. Jones, Hawaii is not a huge market by any means, but nevertheless one worthy of serious consideration. Prosperous countries always offer attraction to the automobile maker and his sales forces, and there is no denying the prosperity of our first overseas holding. Practically every financial interest in the islands is centered in sugar, and the last few years have been ones of great prosperity for the sugar growers. It is only necessary to survey the records of the various companies since about 1913 to realize this fact.

The Securities Manual issued by the Honolulu Stock and Bond Exchange under date of May 15, 1917, shows that 12 sugar corporations, with an average capitalization of \$3,187,500, paid dividends of 12.8 per cent in 1914, 23.8 per cent in 1915, and 35.2 per cent in 1916. These figures are not cited to boom Hawaiian sugar stocks, for they are the figures for only 12 companies out of 24 listed, and they make the best showing. Some of the others were less prosperous, but the figures given indicate why Hawaii is buying automobiles. Capital stock of the sugar companies is traded in rather generally and much of it is held by men in other lines of business. These sugar profits also affect many other lines of trade in the islands.

### The Automobile Population

That this assists the automobile trade is conclusively proven by the following customs figures showing shipments from the United States during the years 1914 to 1917:

Years	Number	Total value	Average value
1914 .....	939	\$961,677	\$1,024
1915 .....	1,381	1,482,622	1,074
1916 .....	1,678	1,672,190	997
1917 .....	2,087	1,941,820	935

It is evident, therefore, that Hawaii is taking a larger number of cars each year, and that the average price of these cars is being reduced each season, an intimation to the makers of the lower-priced cars that the field has attractions for them.

Hawaii has felt shipping conditions as keenly as terri-

tories much farther away, and it is literally true that for the past year and a half the selling of motor cars has been more a question of getting deliveries than of finding buyers. This condition is proved by the fact that one company which received a shipment of 30 cars, having a list price in the United States of over \$1,500 each, disposed of the entire shipment within 10 days after arrival last fall, and difficulties have, of course, considerably increased since then.

Motor vehicles are used to a large extent on four of the islands. Oahu has approximately 3400 cars at the present time, Hawaii 1500, Maui 800 and Kauai 580. There are probably over 30 motor vehicles on the other islands.

### Selling Methods

Doing business with Hawaiian dealers is so nearly identical in every detail with business with any distributor in America that it needs very little comment. The manufacturer doing business with any of the established companies on the islands would be safe in drawing his drafts just as he does on a rail shipment to any distributor in the United States. However, most companies treat the shipments as export business and require payment against steamer bill of lading at point of shipment, although some manufacturers handle the territory as subsidiary to the San Francisco branch or distributor. It is fully worth a direct factory contract.

Honolulu is, of course, the commercial center, and headquarters for distribution must be established there. Some of the larger dealers have branches at Hilo to handle the business on the island of Hawaii. To secure the trade on the other islands, either a resident agent is appointed, who stays in the territory at all times, or a salesman from the Honolulu establishment makes regular trips for the purpose of closing retail sales. One car manufacturer has an independent contract with a Hilo dealer, as well as one at Honolulu, but in most cases the business can be handled as satisfactorily by turning over the whole territory to a Honolulu dealer.

### Used Cars on Hand

Possibly 50 per cent of all sales made on the islands are contingent on the taking of a used car. As a consequence, the disposal of secondhand cars has become a matter of serious worry to the dealers. Within the last year several such cars have been exported to Japan. The dealers claim that they are endeavoring to foster this business by taking precautions to see that the cars are in good condition when shipped.

The higher-priced cars are sold almost altogether on a cash basis. An exception to this rule is found among Hawaiian and Japanese who are driving their own cars in rent service. The machines bought for this purpose are generally big seven-passenger cars which in the United States sell for \$2,000 up. These drivers prefer

to buy new cars, paying for them on a monthly basis and giving the old car as the first payment. Some of the secondhand cars in good condition find an outlet in this field.

Buying of the lower-priced cars, that is, cars listed at less than \$1,000 in America, is done largely on a payment basis, usually one-half cash and the balance within one year. This condition is one that requires a considerable amount of capital in the operation of the business. Instances can be cited where men, impressed with the possibilities of trade in Hawaii, have invested the greater part of their capital in buying and bringing in sample cars, only to find upon studying conditions that a far greater amount of money would be required to establish the business.

There are many inducements to impel and almost demand the ownership of a car in Hawaii. Distances are not short. Honolulu itself has good street car service, but there are many points that can not be reached conveniently by trams, and the motor is preferable in going to the beaches, various army posts, and the country club. On the other islands practically all transportation is done by private vehicles. The distances between plantations and the sugar mills are considerable, and, of course, the motor car cuts down time. Nearly everyone looks forward to the ownership of a car at as early a date as possible.

Road conditions generally may be classed as very fair. Residents complained bitterly over the conditions of some of the highways, but on the whole they are not bad. A considerable amount of road work is being done in all the islands.

#### Trucks Are Gaining

The value of the commercial motor vehicle is fully realized by the business men in the territory. In the cities of Honolulu and Hilo these vehicles are superseding other means of hauling, just as they are in cities on the mainland and in practically the same proportion. Numbers of trucks are used by the army transport service.

In the outlying districts the sugar companies have found trucks suitable for at least two purposes up to the present time, namely, the hauling of laborers to and from their work and the carrying of supplies. Some of the plantations cover large areas. The employees, of

course, are scattered, and when work is to be done at a distant point, trucks are usually assigned to pick up the workers each morning at some given assembling place and carry them to the fields. The plan has been found to pay well, for the workers reach the fields in better condition for work than if they had been forced to walk several miles. They get to work earlier and also work later, the truck calling at the end of the day to take them back to their homes.

#### Tractor Field Is Slow

More difficulties beset the tractor, and its introduction in the islands will be considerably slower than in the case of trucks. This, the planters claim, is due to the fact that sugar land must be plowed to a depth of 18 to 22 inches. The method now generally employed in plowing is to place two large Fowler tractors on either side of the field, attaching the plow to a cable connecting the tractors and draw the plow from one side of the field to the other. The cable is wound on drums on the tractors. In this way the desired furrow depth can be attained, and no other method as satisfactory or economical has yet been devised. There is a possibility of the use of the smaller tractors in harrowing. For the transportation of the sugar cane after it is cut the railroad system is employed. Some plantations have as much as 80 miles of track laid through their grounds. These narrow-gage tracks take but a minimum of space and offer the best means of bringing the cane to the mills.

#### Agricultural Possibilities

Some of the American tractors are suitable for the cultivation of pineapple land, and there is a field here for their use, as the plowing is not so deep as that required on cane land. Much of the pineapple land is hilly and the tractor must be well motored to do the work. A small caterpillar tractor was brought into the islands within the past year, but too recently to make possible any conjecture as to its ultimate success.

The market for accessories, tires, and other requirements is identical with that in the United States for an equal number of cars. The dealers now established have very attractive showrooms and good garage facilities and are fully worthy of the best attention of the manufacturer.

## Increasing Tractor Accessibility

*HERE is a steering gear placed where it can be reached easily and conveniently for adjustment or repair. While it is not practicable to place the steering gear outside the frame of a passenger car or truck there seems to be no reason why, in most cases, it can not be done in tractor building. It's a point worthy of the careful consideration of all tractor designers.*

# Relative Efficiency of Male and Female Operatives

## A Comparison of the Output of Women and Men on Similar Work—A Study of the Experiences of 127 Manufacturing Establishments in the Metal Trades

**W**HAT is undoubtedly one of the most comprehensive and exhaustive investigations into the present extent and the possible extension of the employment of women in industries in the United States, and one of the most thorough and informative presentations of results obtained from such research effort, is covered by and embodied in the report of the National Industrial Conference Board on the wartime employment of women in the metal trades.

As was mentioned in a recent issue of *AUTOMOTIVE INDUSTRIES*, the association of manufacturers' associations, because of the importance of the metal trade to the conduct of the war, and the widespread desire of manufacturers to obtain all available information concerning the employment of women as operatives in metal working plants, began, early this summer, an investigation on an elaborate scale to determine the extent to which women have so far been substituted for men, or introduced as additional workers into the industry, their relative efficiency, wages, working conditions and other factors such as attendance, labor turnover and the necessary and desirable changes in plant and equipment which have been indicated by experience.

Some 600 selected establishments were furnished with a questionnaire, and the results obtained from this source were supplemented by field inquiry and observation. Approximately 330 establishments replied to the questionnaire, but of these only 131 employed female labor in manufacturing processes. In these 131 establishments there was a total working force of 384,709, of whom 49,831 were women and 334,878 were men. Women, therefore, represented 12.9 per cent of the total.

While a number of the employers who responded to the questionnaire indicated in their replies that they contemplate a reorganization of their plants in order to fit them better to utilize the increased number of women whom they expect to employ in the near future, it did not appear from the data obtained that there has been so far any great increase in the number of women used in the manufacturing industries, except in a relatively small number of companies, and more especially in those which are engaged in the manufacture of war materials.

It is not possible, says the report, a part of which is reproduced verbatim in the following paragraphs, to determine what percentage of the total number of women employees in the 131 establishments has been added or substituted on work performed by men previous to August, 1914. From 96 establishments which furnished definite figures on this point the women added or substituted during the period since that date numbered 10,801 out of a total of 34,667 female employees, or 31.2 per cent; 5100, or nearly 50 per cent, have been added or substituted in ten munition establishments.

Table No. 1 as given here is compiled from replies received from 10 concerns in the automobile and automobile accessories field. These concerns employed a total of 78,400 men and 3690 women. Of the women, 1673 had been added or substituted on men's work since August, 1914.

Table No. 2 classified the establishments from whom answers to the questionnaires were received, according to the relative efficiency of men and women workers as measured by output on the same respective processes.

Eliminating the 28 establishments in which, for one reason

or another, no comparison can be made, this summary indicates that the output of women compares favorably with that of men, since it appears that in 30 establishments of the remaining 99 the output of women was greater than that of men in all operations on which both were engaged; in 6 it was greater in some, equal in others; in 30 it was equal to that of the men. In other words, in 66 establishments, or two-thirds of those furnishing definite information as to output, women's production was equal to or greater than that of men in the operations on which both were employed. In only 15 establishments was it found that women produced less than men in all operations on which they were engaged. Their production in the remaining 18 establishments, although less on some operations, was equal or greater on others.

### Relative Efficiency of Men and Women

It appears, moreover, that the efficiency of women did not depend on the nature of the industry as such, or to any marked extent on the fact that they had but recently been

TABLE NO. 2—SUMMARY COMPARISON OF OUTPUT OF WOMEN WITH THAT OF MEN ON SIMILAR WORK BY INDUSTRIES

(National Industrial Conference Board)

Classification of Establishments	Output of Women							
	Total number of establishments	Greater in all operations	Greater in some operations, equal in some	Equal in all operations	Greater in some operations, less in some	Equal in some operations, less in some	Less in all operations	Not comparable or not stated
Total .....	127	30	6	30	7	11	15	28
Automobiles and automobile accessories ..	10	1	..	3	1	2	1	2

Miscellaneous metal products .....	20	3	2	2	1	..	4	8

introduced into an industry. In none of these classifications do a majority of establishments report women always less efficient than men, and it is significant that in the manufacture of foundry and machine shop products, on which women were in the past seldom employed except as core-makers, 24 establishments report women's work equal or superior to that of men in all operations, as against 5 finding them inferior.

Analysis discloses that among those operations which some employers reported women to be performing less efficiently than men, there are very few which are not being carried on with much success by women in other establishments. For instance, in one automobile factory women are found inferior to men in light bench and machine work; yet in a similar factory and in many others doing similar work their output

**Table No. 1—Relative Efficiency of Male and Female Workers**  
A Comparison of the Wages and Output of Women and Men in Ten  
Plants in the Automobile Industry

*Prepared from Data Gathered by the National Industrial Conference*

Serial Number and Product of Establishment, and Number of Men and Women Employed (a)	Number of Women Added or Substituted on Men's Work Since August, 1914 (b)	Occupations of Women (c)	Wage Rates of Women Compared with Rates of Men so far as Reported	Abstract of Employer's Statement as to Wages	Abstract of Employer's Statement as to Output
<i>No. 1</i> Automobiles 12,021 men 815 women	390	Drill press Gear machine Lathe Milling machine Punch press Coremaking  <i>Sewing machine</i> BENCH WORK Inspecting Stock room attendant Tool room attendant		Women do not receive same rate of pay, because it is necessary to provide extra help for handling stock and setting up machines; average earnings for female help as compared with male are about 60% to 65%.	Women as efficient as men on drill presses, light bench-work, and light inspection; on punch presses approximately equal, but necessary to provide die setters, start machines and place stock so that women do not do lifting. In light stock handling about as efficient; on medium heavy bench work 75% to 80% as efficient.
<i>No. 2</i> Automobiles 9,034 men 461 women	277	Drill press, light Lapping machine Shaving machine Milling machine Bench work Stock room attendant	Time, less	Women receive two-thirds men's day rate on same job, but same premium. Piece rates not stated.	On machine work, not as efficient as men, because women lack mechanical knowledge; on stock handling, inspection, etc., sometimes better than men, more thorough and careful.
<i>No. 3</i> Automobiles 32,954 men 371 women	100	<i>Machines, light</i> Bench work, light Putting covers on coil units and testing	Time, equal	No women on piecework.	Women do 10% less than men; though faster, they have less endurance.
<i>No. 4</i> Automobiles 836 men 105 women	Not stated	Machines Bench work Inspecting		Wages of women same as those of men, considering character of work.	Output of women same as that of men.
<i>No. 5</i> Automobiles 5,629 men 315 women	72	Sewing machine Coremaking		We aim to pay practically same for output as when men were on the job. On sewing machines men made about 45¢ per hour; women earn about 35¢.	Women on sewing machines do slightly less than men; on light coremaking, as much as men did formerly.
<i>No. 6</i> Automobiles 875 men 89 women	11	<i>Sewing machine</i> Pasting Back stuffer Inspecting		Women receive less pay than men.	
<i>No. 7</i> Automobile accessories 1,250 men 450 women	300	Drill press Lathe, hand screw Lathe Milling machine Slot machine	Piece, equal	Time rates not stated.	Equal.
<i>No. 8</i> Automobile signals 285 men 100 women	100	Drill press, light Foot press, light Power press, light Assembling	Piece, equal	No women on time work.	Equal.
<i>No. 9</i> Automobile bodies and aeroplane bodies 6,350 men 150 women	Not stated	Sewing machine aeroplane upholstery  <i>(By Departments)</i>			Too early to judge.
<i>No. 10</i> Automobiles 9,166 men 834 women	423	Drill Gear Mill Press Auto B & S Threading Inspection Tool room Tool repair Tool store  Indirect material Fitting Motor Transmission Trimming Store Carpenter Receiving Stock Repair Shipping	Piece, equal	Almost all women engaged in machine work are paid piece rates, their rates being invariably same as men's. Women assemblers and miscellaneous employees are paid by the hour, commencing at 25¢ and raised according to ability. Time rates not stated.	Women's output almost invariably greater, in some cases disproportionately greater, than men's.

**Explanatory Notes:**

- a—The figures in this column include clerical employees, in the majority of establishments.  
b—The figures in this column include clerical employees in a few cases, but their number is practically negligible.  
c—*Italics* in this column indicate occupations on which women were employed previous to August, 1914, and on which their employment has been subsequently extended; Roman type indicates occupations on which women have been newly introduced since August, 1914. Clerical occupations are not designated.

on the same processes is equal to or greater than that of the men.

An aeroplane manufacturer reports that women produce only half as much as men in assembling work or in welding, or in operating drills, punch presses, and hand millers; yet in other factories women have been found to excel men in all these operations except welding, and in welding at least one establishment has found them equal to men. Sorting and packing, reported as being done less rapidly by women in one machine tool establishment, are occupations in which they had already achieved marked success elsewhere.

The success reported in these cases suggests that extended experience, improvements in management, or other changes, might insure to those plants where the output of women falls below that of men the same good results that are now secured by others in their lines.

Among operations which are nowhere reported to be performed as well by women as by men are chipping castings, machine filing, lapping gages, and brazing. The first two are somewhat heavy work for women. Women were doing machine filing in only two and brazing and chipping castings in only one of the establishments reporting.

#### Experience of Individual Establishments

Further light is thrown on the question by the statements of employers as to the operations successfully performed by women. In one automobile establishment women are working on shaving machines, milling machines, light drill presses, and lapping machines, and are doing bench work, light assembling, stock handling and inspection of small parts. In regard to their output it was stated:

On productive work, women as a rule are not as efficient as men, due to the fact that they have no mechanical knowledge of machines and do only what the job setters show them; also, on assembly work they take longer to understand the proper fits, etc., than a man. On nonproductive work such as stock handling, inspection, etc., the women are as good as the men, in some cases much better, as they are more thorough and careful. This is particularly true of the light work.

In another automobile plant, where women are employed in 23 departments doing the same types of work enumerated above and performing other tasks formerly carried on by men, they give still greater satisfaction:

The comparative output of women on the same process is almost invariably greater than that of the men, in some cases quite disproportionately so. In some cases, notably on a nut tapping machine, a woman was put on and at the end of the week she had turned out about double the quantity of the man working next to her, and after endeavoring to equal her speed for a few days, the man quit, and was replaced by another woman who is now very nearly the equal of the first. We find, particularly in assembly work, that the women are much more conscientious and painstaking than the men.

The report of a gear manufacturing establishment where women are sand blasting very small castings and performing grinding, drilling and broaching operations indicated that their output is from 15 per cent to 25 per cent higher than that of the men.

An unusually striking instance of the efficiency of women in metal trades work appears in a recently published statement of a New York gear manufacturing concern:

On our three-inch Gleason generators, the largest day's production turned out by our best men operators on differential side gears was 91 pieces, and on differential pinions, 260 pieces for a nine-hour day. The slowest woman operator in point of production equals the best day's product by the men, and our speed merchants, as we call them, turn out 126 side gears and 320 differential pinions in a nine-hour day, an increase of 35 side gears and 60 differential pinions.

On our 24-inch Fellows gear shapers the women turn out from 20 to 30 more pieces in a nine-hour day than the men.

On our filing and burring machines, the women are far ahead of the men on production and accuracy. They overrun the men about 250 pieces in nine hours, and the small amount of work rejected by the inspectors is surprising, as compared to the amount that the inspecting department rejected when the same machines were operated by men.

On our drill press work is where our women really shine. In one case they have increased the production 1200 pieces in a nine-hour day. The case I speak of is putting on a radius and reaming the bore of differential pinions. This requires two operations on a two-spindle drill press, one operator putting in the radius and the other reaming the bore. The largest production turned out by two men was 3200 pieces each; to date, two women have turned out 4400 pieces each in nine hours, under exactly the same conditions, and it is hard to tell where they are going to stop. We have one woman who drills two 5/32 in. oil holes 3/4 in. deep and one 1/2 in. hole 1/2 in. deep in 246 stem gears in nine hours; this is 50 more pieces than the men ever turned out.

One of the most conspicuous examples of success with women workers is offered by an establishment employing

5000 women in practically all mechanical operations required in the manufacture of fuses. On the basis of time studies, a maximum of 375 standard pieces per day had been set for male turret lathe operators, who were turning out an average of 190 pieces; when women were employed on this work they produced 531 pieces. In the assembly department, where 2000 girls are at work, the estimate by two sets of engineers for the best possible production by men was 15,000 complete fuses daily in two shifts; the average output actually obtained when women were employed was 38,000 per day in one shift. In this case, however, the excess of output actually obtained over the estimates was so great as to leave little doubt that some other factor than the superior efficiency of women was involved. The president of this company considers the endurance of women, as well as their rapidity, superior to that of men:

In spite of the amount of work they do, they are not overworked. In fact, they seem to be able to keep up their high rate of speed better than the men. In one of the assembly departments, for instance, we tried men on a particularly trying job. At the end of three days they came to us and told us that the work was too strenuous. We put girls on the benches, and since then there has been no complaint.

In a steel establishment where women are employed in manufacture of fuses, women operators of drill presses and milling machines are found to be from 25 per cent to 50 per cent faster than men. Another manufacturer of small metal parts for munitions stated that women drill press operators handle 196 parts per hour on daywork while on nightwork men turn out only 148. Although the output on a day shift cannot fairly be compared with that on a night shift, this would not explain so marked a difference in results. In a bolt and nut establishment women working on drill presses and milling machines have achieved an average increase in output amounting to 30 per cent.

An especially interesting illustration of the variety of work of women in railroad shops is given by a woman who has risen from mechanical work to an important executive position. In one of these shops women were employed as follows:

1 milling machine operator	6 car preparers
2 coremakers	4 upholsterer helpers
1 chipper	2 carpenter helpers
1 tinsmith helper	1 locksmith
1 rivet heater	2 lacquerers
1 ordinary drill operator	1 turntable operator
1 tool dressing helper	4 yard laborers
4 hammer drivers	

In another, women were, in addition to these occupations, operating cranes, lathes and boltheaders, and grinding drills. With regard to their efficiency it was stated:

The comparative output of men and women on the same processes varies with the type of work. Usually the output is similar. One foreman said: "In quantity less; in quality women put out superior work."

Some incidental advantages mentioned by various manufacturers are pertinent in considering the introduction of women workers. Women are commended as being more thorough and conscientious than men, as spoiling less work and as being more careful of tools. Even where the quantity of their work is less than that of male workers, the quality is frequently reported as better. Another valuable characteristic sometimes referred to is the regularity of women's output. A bolt and nail manufacturer employing women on pointing bolts, thread cutting, nut tapping, filing, papering and packing bolts, reported their output as at least 10 per cent larger, and added that the quantity can be depended on from day to day.

#### Absence of Restriction of Output

The reported superiority of women in some of the instances cited was so great as to suggest that restriction of output by men may have played a part in raising the comparative efficiency record of women. Certainly there is a strong probability that where phenomenal increases of output were obtained by women workers the men had not been working up to their capacity. The information obtained on this point was not sufficient to warrant conclusions. Evidence from other sources, however, suggests rather definitely that women are less inclined than men to practice arbitrary restriction. A statement made by the president of the British Iron and Steel Institute is pertinent:

When it was found that the demands of the government for a greatly accelerated production of shells required the employment of girls in the projectile factory, owing to the scarcity of skilled workers, these girls in all cases produced more than double that by thoroughly trained mechanics—members of trade unions—working the same machines under the same conditions.

In the turning of the shell body the actual output by girls with the same machines and working under exactly the same conditions and for an equal number of hours, was quite double that by trained mechanics. In the boring of shells the output was also quite double, and in the curving, waving, and finishing of shell cases quite 120 per cent more than that of experienced mechanics.

Restriction of output by male workers in Great Britain before the war was admittedly very common; a large proportion of the increased production in that country is to be attributed to the absence of restrictive practices among women workers.

Yet in many types of light work women apparently are capable of bettering men's record even when the men do their best.

#### Present Limitations of Women's Efficiency

In reviewing this record of efficient performance by women it must be emphasized that most of the tasks on which they are engaged are semi-skilled work of repetitive character, in which rapidity, lightness of touch, and natural dexterity are more important than skill acquired through long training and experience.

The reports of employers often refer to the special deftness of women in handling small repetitive work, and in numerous plants departments have been arranged to secure a better routing of material and a subdivision of tasks which offer a maximum of light repetitive operations. This is doubtless the most direct road to the immediate successful utilization of female labor.

It is too early to form conclusions as to the ability of women to perform work of higher skill. The necessity for immediate increase of output made it essential to give women specialized training for particular jobs rather than to develop them into general mechanics. Even in England, where in one place or another women are used in practically all operations in the engineering and munition trades, they have not received the broad general training which skilled workmen are given. Opinions of English employers have undergone considerable change during the course of the war. Although the subdivision of the processes has secured most remarkable results, women collectively are doing much more than mere repetition work. According to one British report:

Women have entirely destroyed our pre-war ideas as to what constitutes "skilled" work. When in the early days of the war women were trained to turn out 19 pdr. H. E. shell and equal the production of male labor, many thought that such work, amounting as it does to a little more than manipulative dexterity, was about the limit of the capacity of women who had not received a regular course of engineering training. After a few months workshop experience, however, women are to-day building the greater part of one of the best high-speed engines in the country, each woman setting her own tools and work, and able to machine any piece of work that the tool she is on will take.

Women are doing magnificent work both in regard to accuracy and output.

It should be emphasized, however, that even where women are doing such work as setting up, assembling, or performing machine tool operations, they have been trained for a particular type of machine and for a limited range of operations. How far the present limitations of women workers, noted by both American and British manufacturers, might be overcome by broad technical training cannot be determined from experience now available.

#### Wages

The following summary indicates the wage policy of establishments furnishing data for this investigation as reported in replies to the schedule of inquiry.

In this table the column headed women's rates "Equal to men's" means that rates were the same for men and women whether on piece or day work respectively; in some cases women were engaged exclusively on piecework; in other cases on time work. The establishments listed in the column headed "Less than men's" also sometimes employed women exclusively on either piece or time work. In a few cases, as stated in the footnote, complete information was not furnished. Again, the operations were sometimes modified so that the work done by women, while similar to that done by men, was not identical; for instance, additional help was pro-

vided or only the lighter part of the operation performed by women. In such cases piece rates paid women frequently were lower than those paid men; in some other cases women were paid lower time rates.

TABLE NO. 3: SUMMARY COMPARISON OF WAGE RATES OF WOMEN WITH THOSE OF MEN, BY INDUSTRIES

(National Industrial Conference Board)

Classification of Establishments	Total Number of Establishments	Wage Rates of Women			
		Equal to Men's	Piece Rate Equal to Men's, Time Less	Less than Men's	Not Comparable or Not Stated
Total.....	127	53	29	24	21
Automobiles and automobile accessories...	10	4*	1	3†	2
Typewriters and other light machines.....	6	2	2	2	
Electrical machinery, apparatus, and supplies.....	18	3	2	8‡	5
Foundry and machine shop products.....	37	18**	8	7	4
Munitions.....	13	5	6	..	2
Railway equipment....	7	6	..	..	1
Tools, cutlery, and hardware.....	16	9	3	1	3
Miscellaneous metal products.....	20	6	7	3	4

\*In two cases time rates not stated.

†In one case piece rates not stated.

‡In one case time rates not stated.

\*\*In some cases piece rates equal.

‡In one establishment some piece and time rates are less.

Excluding the 21 establishments for which there was no basis for comparison, this table shows that in 53 of the remaining 106 women received the same rates of pay as men, whether on time or on piece work; in 29 women's piece rates were the same as men's but their time rates were lower; in 24 both piece and time rates were lower. It may be noted in this connection that the U. S. Department of Labor has declared itself in favor of equal wages for women performing the same work as men on Government contracts, and that a similar position has been taken by the Director-General of Railways in ordering the recent wage increases and by the National War Labor Board, which has defined its policy in the following terms:

If it shall become necessary to employ women on work ordinarily performed by men, they must be allowed equal pay for equal work.

#### Equal Wages for Equal Work

The principle of equal wages for equal work found especially marked recognition among employers in those industries where the employment of women is a comparatively new feature. For example, 18 establishments manufacturing foundry and machine shop products pay women equal rates in all cases where they are performing the same work as men, while 8 pay them equal piece rates. In the munitions industry, 5 establishments pay equal rates and 6 others pay equal piece rates but lower time rates. The relatively large number of cases where women receive lower rates in electrical manufacturing probably is due to the fact that women have been employed in this industry for a much longer period and that certain occupations came to be regarded as women's work when the principle of equal wages was seldom accepted.

Where the wages of women were less than those of men, the difference usually was from 10 per cent to 25 per cent, although in seven establishments there was a still greater difference. Various reasons were assigned for this lower wage scale. One machine tool manufacturer declared that it was the intention to pay equal wages as soon as the cost of changes made to allow the introduction of women has been recovered. Some stated that women's wages are gradually being increased as they become more efficient, with the intention of ultimately making them equal to those of men. In several places women are paid a lower time rate while learning, after which they receive equal pay on a piece-rate basis.

Another reason offered for lower wages to women is the necessity of providing them with helpers to set up machines, to make repairs, and to bring up stock, or of introducing specially adapted tools.

The preceding discussion refers to rates of wages and not to earnings, which may differ although rates are equal, either on account of the individual capacities of the workers, their endurance, the hours of work, or for other reasons.

# Making War Maps by Camera

Airplane Needs Skillful Piloting While Photographer Works—Color-Sensitive Plates Used in Non-Focusing Box-Type Apparatus

## PART II

**A**ERIAL photography is not in itself a particularly safe occupation. Leaving an aerodrome, equipped with a camera and supply of plates, the machine climbs toward the enemy line, and almost instantly encounters the archies, the anti-aircraft guns, which are always on the lookout for reconnaissance machines. As a rule, these encounters are a sort of continual match between the pilot's ingenuity and the anti-aircraft gunner's power of prediction. The gunners must guess where the pilot is going in order to allow the time necessary for his shells to reach the machine. The pilot usually takes a side slip, but when he is taking overlapping photographs this is impossible, and he evades the gun by manipulating his throttle, slowing down if the gunner is firing much ahead of him, or speeds up if the shells are behind him. Following a photographic reconnaissance the negatives are turned over to the photographic section immediately upon arrival at the hangar, and are developed and printed almost as quickly as the plane is pushed into the shed.

### Automatic No-Focus Cameras Used

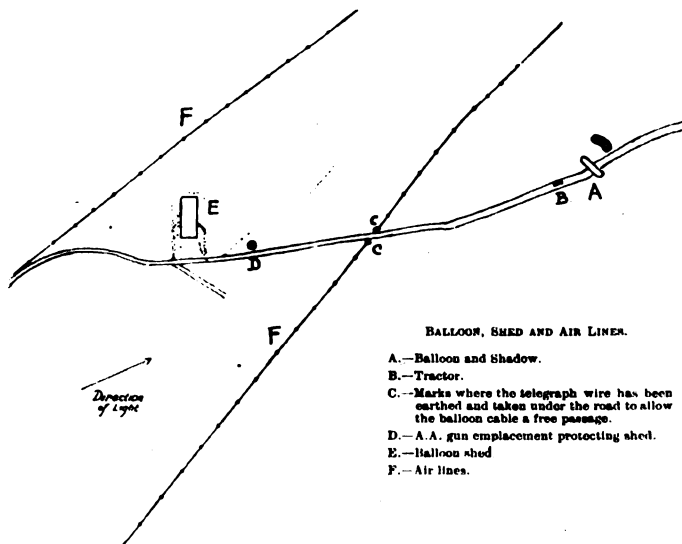

During the first months of the war, ordinary cameras were used, but the leather bellows were found disadvantageous, because they were blown in by the great wind pressure. Focusing cameras were found inefficient. Changes resulted in automatic cameras, with the focus at infinity, requiring no focus adjustment, and constructed in a box type without the leather bellows. Plates are changed automatically as quickly as the photograph is taken, either by the use of small propellers, electricity, or clock mechanism. This gives the pilot less detail work and allows him to take his photographs while at the

Stores of batteries. A shows the typical German stationary anti-aircraft gun pits with concrete pedestals in the center for gun mounting. B shows the ammunition pits and the dugouts connected by short lengths of trench. C shows the dugout from the trench for the personnel

A very interesting photograph, showing a balloon, tractor, balloon shed, gun emplacements and an air line. The balloon is reflected in the photograph by a small white sausage-shape and is made readily discernible by its shadow on the ground, which proves that it is an object suspended in the air. The tractor B, although discernible in the original photograph, is not clear in the reproduction

same time watching for enemy aircraft. An important need in aerial photography to-day is a satisfactory automatic film camera which will eliminate the need for glass plates and allow greater numbers of photographs to be taken. At first, the fastest types of plates were used, but owing to the flat results obtained and to the invariable ground mists in Europe, color-sensitive plates, such as panchromatic plates with yellow filters, were used more advantageously. Small 4 x 5 plates were used at first, and enlarged, but the use of larger plates is now approved.

The photographs accompanying this article and the maps made from them are taken from an instruction book for the Intelligence Division of the British Army. This book is the first of its kind and some idea of the tremendous importance of this branch of the army is reflected in the character of the illustrations and the interpretative diagrams. During the recent Allied offensive it was not uncommon to have a print before an officer planning an attack less than 45 minutes after the plate had been exposed.

*Fortified shell holes in No Man's Land. The letter A shows the German front line trenches. B indicates the track between the front line trench and the fortified shell holes in No Man's Land. C marks the net of organized shell holes. Using a photograph of this sort an artillery commander directs his artillery*

*This interesting photograph and sketch map of buried cables and air lines show clearly how the intuition of a Sherlock Holmes is essential in interpreting aerial photographs. In the diagram the letter A indicates small dots which show as black spots in the illustration. The interpreters of the photograph decided that these black spots represented parts of a farm which the farmer did not plow. They figured that he did not plow them because there were obstructions, such as poles. Because the poles were regular in their formation they decided that it was a telegraph or telephone air line of communication*

Network of trenches showing the listening and observation posts. It is by the use of photographs like this that the infantry commanders make their night raids over the top for prisoners. The photograph shows the exact location of the enemy. The raiding party knows accurately how to surround the posts without suspicion

Interpretation of Air Photograph, Showing German Field Wireless Station Near Lepelhem

1. Air Photograph No. 48 N62, dated 17th July, and taken at 8 a. m., shows a German field wireless station. The reasons for arriving at this conclusion from the examination of the photograph are as follows:
  - (a) The shadows cast by a pole protruding from, or in the vicinity of, a hut.
  - (b) Double heaps of soil at regular intervals of 90 deg., suggesting the pits made in chalky ground for anchoring the guy ropes supporting the pole.
  - (c) A double circumference of pits, enclosing the station, which is of the "Umbrella" type, i.e., composed of a series of wires forming a cone.
  - (d) Bridge and track used by only a small personnel, as shown; also by the undisturbed grass, except in the immediate vicinity of the hut.
2. The height of the pole has been calculated at 120 feet to 125 feet. The height of the sun at 8 a. m. on the 17th of July was 24 deg. The necessary corrections have been made for summer, local time, etc.

# Greater Engine Efficiency Demanded

War Economics Require We Stop 70 Per Cent Waste of Thermal Efficiency in Waterjackets and Exhaust

CLEVELAND, Sept. 21.—President Charles F. Kettering started the winter circuit of S. A. E. Section meetings here to-night by one of his interesting talks on aviation, engine fuels and other matters dear to his heart. As in other talks, he did not mince matters and struck straight from the shoulder.

"The internal combustion engine is understood in general, but in fuel and efficiency problems special attention must be focused on it. Our engines are not efficient. We must design engines that will use fuel more economically and not throw away 40 per cent of its thermal efficiency through the water jackets and 30 per cent through the exhaust, as is done to-day.

"In considering the motor and the fuel the engineer must think fundamentally. Given an engine he must make fuel to fit it. Tests were made at the Dayton laboratories with various kinds of fuel. One test was made to find out why kerosene could not be used. These tests disclosed that kerosene knocks were not premature. They always occurred 20 deg. after the piston was on its downward course and 50 deg. after ignition.

"Observations were made through a glass-covered opening in the cylinder and every knock displayed a carbonized flame within the casing.

"There is much talk of the airplane industry after the war. It may or may not be a great development. The present cost of an airplane engine is from \$10 to \$20 per horsepower. This is quite high. If someone can design one at a couple of dollars per horsepower a great future is in store for the industry.

"The fundamental problems in airplane construction are weight, horsepower and fuel consumption. These travel in a circle. If it is desired to increase the carrying capacity of a machine while maintaining a given ceiling, larger wings are needed. This, in turn, demands increased horsepower, which necessitates the use of more fuel. This again adds to the weight and the wing surface must be again enlarged, and so on. The problem resolves itself into one of fuel economy and decreasing the weight of the engine.

"The Liberty engine weighs 825 lb. It is necessary to carry 0.7 lb. per horsepower for cooling, making a total of 280 lb. The question is, first, how much weight per square foot is the plane intended to carry, and next, what is the maximum of speed of travel desired? That will determine how much engine is required.

## Commercial Airplane Possibilities

Whether or not future airplanes will carry freight depends upon what the cost can be made per ton mile. Should we arrive at a satisfactory cost it will be necessary to establish airplane roads to guide the planes. Being at a high elevation, pilots of planes would experience difficulty in identifying markings (numbers) on the ground or on top of structures. In unsettled weather conditions they would be traveling above the clouds, making this method of markings further ineffective. The only manner in which planes could be efficiently directed over a route would be by wireless. Each station would have its own number which would be caused to register as the plane passed over it.

"Practically all the laws of aerodynamics are clear. Stresses are understood; materials are known, although there may be a question as to whether metal or wood is better. Someone may come along with a new treatment of metal which may revolutionize the whole thing."

President Kettering mentioned the untruthful reports that came back here following the arrival in Europe of the redesigned De Havilland 4. He declared that Pershing as a matter of fact did not know they were there.

The reports claimed that this type of plane would be unsatisfactory because the gas tank was not large enough, because the wing covering was sewed on improperly, because there was the wrong kind of splice and because there was no stabilizer brace on the tail (which later was affixed). Shortly afterward, however, word was received that "since the above telegram was sent it has been given by direct information that the D. H. plane is the best and that the Liberty engine is the best in Europe. To-day airplanes are given priority above food and soldiers. It is said that if the war lasts 2 years more the Liberty engine will be the only one used. One thousand engines are going over every week. At first two spares were sent over for every plane, later two engines were sent for two planes, and soon it will not be necessary to ship spares; every engine will mean a plane. By Jan. 1 1200 planes a week will be shipped.

Their average life at the front is 60 days.

It now takes only 14 days from the time the tree is cut for a piece of wood to be turned into a wing beam, as compared with 9 months a year ago.

## Where Shop Training Can't Be Done

THERE are some shops in which, from the very nature of the conditions that exist, it is impossible to train new employees as they should be trained except in special training departments, says H. E. Miles, chairman of the Section in Industrial Training of the Council of National Defense.

If the spirit of the factory is bad, if there is much confusion, wastage, stalling and nervous strain, then even the simplest thing can better be taught in a special training department.

To illustrate: Four girls were trained (on difficult work, in this case) and on going into the shop earned an average of \$7 the first day, \$8 the second, \$9 the third, and a little later \$11. A sub-foreman then told them that they must stop at about \$6, for the men around them would not stand for more. Nothing could be taught at machines in such a factory work-place; for instruction includes the development of war spirit, speed and accuracy, and must be given in an atmosphere and surrounding surcharged with these virtues. Incidentally, the director of training in this shop says the girls will maintain their \$11 average with the prospect of being ostracized for so doing.

It is said that a barber or street car driver, with a kit of tools of a sort that gave him character, secured a job as a machine hand in a great New England factory and held it for four days before he was discovered. That would be a poor place to train in.

The company has since put in a training department where it instructs at the rate of 50 men per day, two days each, in very accurate machining, but with such perfection of stops and other fool-proof appliances as make two days enough.

In another factory employing some 4000 men and needing 3000 more, an operator called to the foreman, "Come and tell me how to do this." Said the foreman, "Weren't you hired as an all-round toolmaker?" "Yes." "Then, d— you, bore that or get out." He got out and later explained, "I am an all-around toolmaker. I was ordered to bore out a 75-mm. cannon. I never saw one in my life and I didn't propose to spoil the first one for want of advice."

You couldn't teach in such a shop. They plan to put in a training room for simple as well as difficult operations.

# The Theoretical Indicator Diagram

## SECOND INSTALMENT

By O. A. Malychevitch, E. S. A., C. M.

THE following data were obtained by competent investigators:

TABLE III

	Method of De-termination	Type of Engine	Com-pression ratio	Tem-perature T <sub>a</sub> ° abs
Prof. Dalby .....	Pyrometer	Gas engine.	4.6:1	398
Der Oelmotor .....	Pyrometer	Mercedes ..	4.7:1	393
Prof. Hopkinson ..	Deduction	Gas engine.	6.3:1	375

It is desirable that the temperature of the inlet gases be as low as possible, as this item, together with the compression ratio and the thermal efficiency, greatly affects the engine output.

$T_a$ —the inlet temperature diminishes with an increase in the compression ratio, as this diminishes the quantity of burnt gases remaining in the cylinder and the effect of their high temperature.

$P_c$  = the compression pressure:

$$P_c = p_a e^n \quad (13)$$

$T_c$  = the compression temperature abs.:

$$T_c = T_a e^{n-1} \quad (14)$$

where  $p_a$  and  $T_a$  are the suction pressure and temperature abs. respectively,  $e$  is the compression ratio,  $n = 1.35$ .

$P_z$  = explosion pressure:

Applying Charles's law to the working mixture

$$P_c V_c = R_1 T_c$$

and to the burnt gases

$$P_z V_z = R_1 T_z$$

But according to (equation 10),

$$R_1 = \delta R_2$$

So that

$$P_z V_z = \delta R_2 T_z \text{ or}$$

$$\frac{p_z V_z}{\delta p_c V_c} = \frac{T_z}{T_c}$$

If we assume that  $V_c = V_z$  we get:

$$p_z = \delta p_c \frac{T_z}{T_c} \quad (15)^*$$

\*At constant volume:

$$P_z = \delta V_c \frac{T_z}{T_c}$$

$P_c$  = pressure at the completion of the expansion

$$P_c = \frac{P_z}{e^n} \quad (16)$$

$T_c$  abs. = temperature at the completion of the expansion

$$T_c = \frac{T_z}{e^{n-1}} \quad (17)$$

Experiment tends to show that the compression ratio is the only factor having an influence on the temperature  $T_c$ .

Equations (1) to (17) give the necessary data for constructing the theoretical indicator diagram and for calculating the working process of the engine.

Automobile engineers are very skeptical regarding this method and the writer's own experience enables him to appreciate their viewpoint, which is a result of the application of old formulæ without any concentrated effort

\*We know nothing definitely about the temperature  $T_r$ , but it is certain that  $T_r$  depends on  $T_c$ , the temperature at the end of expansion and very probably it is not very much lower than  $T_c$ .

to develop a method for the collection of scientific and experimental data.

We will now work out a practical example, illustrating the calculation of the working process of a four cycle engine.

We will select a four-cylinder engine of 90 mm. bore and 180 mm. stroke (Fig. 2).

Piston displacement .....  $V_h = 1145 \text{ cm}^3$

Volume of compression chamber  $V_c = 286.25 \text{ cm}^3$

Total volume .....  $V = 1431.25 \text{ cm}^3$

Compression ratio:

$$\epsilon = \frac{V_h + V_c}{V_c} = \frac{1145 + 286.25}{286.25} = 5 \quad (18)$$

Pressure previous to compression .....  $P_a = 0.87 \text{ at.}$

Initial pressure of working mixture .....  $p_a = 1.00 \text{ at.}$

Pressure of burnt gases in the cylinder .....  $P_r = 1.05 \text{ at.}$

Initial temperature .....  $T_a = 290^\circ \text{ abs.}$

Temperature of exhaust gases remaining

in the clearance space .....  $T_r = 1070^\circ \text{ abs.}$

Heating value .....  $H_g = 10,500 \text{ cal/kg.}$

Air/gasoline ratio .....  $A = 16:1$

Ratio

$$\frac{\text{specific heat at const. pressure}}{\text{specific heat at const. volume}} = n = 1.35$$

By equation (12):

$$T_c = 290 \frac{5 \times 0.87}{0.82 \times (5-1)} = 380 \text{ deg. abs. or } 107 \text{ deg. C.} \quad (19)$$

By equation (13):

$$P_c = 0.87 \times 5^{1.35} = 7.75 \text{ atm.} \quad (20)$$

By equation (14):

$$T_c = 380 \times 5^{0.35} = 660 \text{ deg. abs. or } 387 \text{ deg. C.} \quad (21)$$

Coefficient  $\psi$

Volume of working mixture at  $p_a T_a$ :

$$V_h \eta_c = V \left( 1 - \frac{1}{\epsilon} \right) \eta_c$$

Volume of working mixture in cylinder at  $p_a T_a$ :

$$V_a = V \left( 1 - \frac{1}{\epsilon} \right) \eta_c \frac{p_a T_a}{p_a T_c}$$

The volume of exhaust gases remaining in the cylinder at  $p_a T_a$  is  $V - V_a$

$$\text{Therefore } \psi = \frac{V - V_a}{V_a}$$

Inserting the value of  $V_a$  and the value of  $T_a/T_c$  from equation (12) we get:

$$\psi = \frac{p_r T_c}{\eta_c (\epsilon - 1) p_a T_r} \quad 22$$

$$\psi = \frac{1.05 \times 290}{0.82 \times 4 \times 1070} = 0.09 \quad (23)$$

By equation (4) we may find the number of kg.-mol. ( $K_1$ ,  $K_2$ ,  $K_3$ ) of the three components of the working mixture and burnt gases.

Reaction I:

Number of kg.-mol. of oxygen required for combustion = 1.

Number of kg.-mol. of carbon dioxide developed = 1.

Change of gas kg.-mol.  $dK = 0$ . (24)

Reaction II:

Water vapor:  $H_2 + \frac{1}{2}O_2 = H_2O$ .

Number of kg.-mol. of oxygen required for combustion =  $\frac{1}{2}$ .

Number of kg.-mol. of water vapor developed = 1.

Change of gas kg.-mol.  $dK = +\frac{1}{2}$  (25)

i.e., the process of forming water vapor ( $H_2O$ ) in burning  $H_2$  gives the increase of volume of gas =  $+\frac{1}{2}$ .

The elements of gasoline are:

Carbon C

Hydrogen H

As mentioned above, we express the working mixture and burnt gases in kg.-mol., taking as a unit the number of kg. equal to the molecular weight of gasoline.

The molecular weight of carbon is 12 and that of hydrogen 2, therefore the number of kg.-mol. of 1 kg. will be:

$$K_1 = \frac{C}{12} \quad (26)$$

$$K_2 = \frac{H}{2} \quad (27)$$

By equation (25) the increase in the volume of gas or kg.-mol. for  $H_2 = +\frac{1}{2}$ . Then the increase for  $H = +\frac{1}{4}$  and

$$dK = +\frac{H}{4} \quad (28)$$

Therefore the sum of kg.-mol. of the components of the working mixture will be

$$K_1 + K_2 + K_3 = \frac{A}{28.89} + dK \quad (29)$$

where  $\frac{A}{28.89} + dK$  is the number of kg.-mol. of working mixture.

From equation (29) we have

$$K_1 = \frac{A}{28.89} - \left( \frac{C}{12} + \frac{H}{4} \right) \quad (30)$$

Substituting the value of equations (3) and (26), (27), (30) in equation (4) we will obtain equation (5).

$$\begin{aligned} C_{mv} &= K_1 \times C_{v1} + K_2 \times C_{v2} + K_3 \times C_{v3} = \\ &= \left\{ \left[ \frac{A}{28.89} - \left( \frac{C}{12} + \frac{H}{4} \right) \right] [4.625 + 0.00053T] + \right. \\ &+ \left. \left[ \frac{C}{12} (6.774 + 0.00189T) + \frac{H}{2} (6.855 + 0.00116T) \right] \right\} = \\ &= (0.160A + 0.180C + 2.271H) + \\ &+ \frac{(0.018A + 0.113C + 0.448H)T}{1000} \quad (31) \end{aligned}$$

This is the equation of the total specific heat of working mixture. It may be applied to the case of fuel naphtha and kerosene as well as to gasoline.

Gasoline consists of 85 per cent carbon and 15 per cent hydrogen, and these elements are mixed with 16 times their weight of air. Substituting these values in equation (31) we get the total specific heat of the working mixture (gasoline).

$$\begin{aligned} C_{mv} &= (0.160 \times 16 + 0.180 \times 0.85 + 2.271 \times 0.15) + \\ &+ \frac{(0.018 \times 16 + 0.113 \times 0.85 + 0.448 \times 0.15)T}{1000} = \\ &= 3.053 + 0.451 \frac{T}{1000} = L + MT \quad (32) \end{aligned}$$

Substituting the values of equation (32), (23) and (8) in equation (9) we get

$$\begin{aligned} &0.70 \times 10,500 + 1.09 \left( 3.053 + 0.451 \frac{660}{1000} \right) 660 \\ &= 1.09 \left( 3053 + 0.451 \frac{T_z}{1000} \right) T_z \quad (33) \end{aligned}$$

from which  $T_z = 2150$  deg. abs. or 1877 deg. C.

From equations (11) and (28) we find:

$$\delta = 1 + \frac{7.22 \times 0.15}{16(1 + 0.09)} = 1.1 \quad (34)$$

From equations (15) and (34)

$$P_z = 1.1 \times 7.75 \frac{2150}{660} = 29 \text{ atmospheres} \quad (35)$$

From equation (17)

$$T_e = \frac{2150}{50.35} = 1200 \text{ deg. abs. or } 927 \text{ deg. C.} \quad (36)$$

For values of  $T_e$  see Table IV.

TABLE IV.

Compression rates ..... 4 5 6  
Temperature  $T_e^\circ$  abs. .... 1100, 1070, 1050

From equation (16)

$$P_e = \frac{29}{5^{1.25}} = 3.3 \text{ atm} \quad (37)$$

Theoretical mean indicator pressure

$$\begin{aligned} p_i &= \frac{p_o}{\epsilon - 1} \left[ \frac{p_z}{p_o} \frac{1 - \frac{1}{\epsilon^{n_2-1}}}{n_2 - 1} - \frac{1 - \frac{1}{\epsilon^{n_1-1}}}{n_1 - 1} \right] \text{ or} \\ p_i &= \frac{p_o}{\epsilon - 1} \left( \frac{p_z}{p_o} X - Y \right) \quad (38) \end{aligned}$$

$$\text{where: } X = \frac{1 - \frac{1}{\epsilon^{n_2-1}}}{n_2 - 1} \text{ and } Y = \frac{1 - \frac{1}{\epsilon^{n_1-1}}}{n_1 - 1}$$

The value of  $X$  and  $Y$  are given in Table V.

n	COMPRESSION RATIO E			
	4.5	5.0	5.5	6.0
1.30	1.20	1.26	1.33	1.38
1.35	1.14	1.22	1.28	1.33
1.40	1.12	1.18	1.25	1.27

$$p_i = \frac{7.75}{4} \left( \frac{29}{7.75} \times 1.22 - 1.2 \right) = 7.5 \text{ atmospheres} \quad (39)$$

Taking into consideration that the exhaust valve begins to open before the power stroke is completed, the pressure of resistance of the suction and exhaust stroke and delaying combustion it is necessary to make correction:

$$P_i = p_i \times \delta \quad (40)$$

where  $\delta = 0.90 - 0.95$ .

$$p_i = 7.5 \times 0.93 = 7 \text{ atmospheres} \quad (41)$$

The fuel consumption per ind. hp.-hour

$$F = 9220 \frac{p_o \eta_e}{T_e p_i A} \quad (42)$$

$$F = \frac{9220 \times 0.82}{290 \times 7 \times 16} = 235 \text{ gr. per hp.-h.}$$

The fuel consumption per C. hp.-h. is

$$\frac{f}{\mu_m} = \frac{235}{0.86} = 275 \text{ gr., and}$$

$$\frac{f}{\mu_m} = \frac{235}{0.62} = 380 \text{ gr.}$$

where  $\mu_m$  = mechanical efficiency = 0.62 — 0.86 (see Fig. 1).

Equations (18) to (42) determine the theoretical indicator diagram presented in Fig. 2.

TABLE VI—VALUE  $\alpha + \beta$  FOR  $n = 1.1, 1.4$

$n +$ Angle $\alpha +$ Angle $\beta$ $\alpha\beta$	1.10 11°30' 0.2-1.5 0.222	1.15 11°30' 12°30' 0.2 0.234	1.20 11°30' 120 0. 0.245	1.25 14°00' 17°00' 0.25-1.4 0.322	1.30 14°00' 18°00' 0.25 0.337	1.35 14°00' 19°00' 0.25 0.352	1.4 18°00' 26°00' 0.33-1.3 0.497-1.2
---	------------------------------------	--	--------------------------------------	---	---	---	--

In Fig. 2 line  $OV$  represents volumes  $V_o = 286.25$  cc. and  $V_h = 1145$  cc. Line  $OP$  represents pressures in atmospheres and temperature in degrees abs. It is advisable to make the stroke of the engine  $V_h = 180$  mm. in our case. From the origin draw the line  $ON$  at an angle  $\alpha$  of 14 deg. 5 m. corresponding to  $n = 1.35$  and line  $ON_s$  at an angle  $\beta = 19$  deg. 25 min. (Table VI).

Draw point  $a$  with a co-ordinate

$$P_a = 0.87 \text{ atmosphere}$$

and

$$V = V_o + V_h = 1431.25 \text{ cc.}$$

Draw the vertical  $aa_1$  and the horizontal  $aC_1$ .

Through the intersection of  $a_1$  and  $C_1$  draw the oblique lines at 45 deg. as shown (Fig. 2) and from the points  $b_1$  and  $C_1$  so determined draw the next set of vertical and horizontal lines. Their intersection at  $d$  determines the next point of the curve. The network of construction lines determines the polytropic line of compression  $ac$ . By the same method the polytropic line of expansion  $ez$  may be constructed.

With calculated values of temperatures, compression and expansion curves we can determine intermediate points of temperature curves  $a'C'$  and  $e'Z'$  by the following equations:

$$T_n = T_o \left( \frac{P}{P_o} \right)^{\frac{n-1}{n}} \text{ or}$$

$$T_n = T_o \left( \frac{V}{V_n} \right)^{n-1}$$

where  $P_o$ ,  $V$  and  $T_o$  refer to the original state of the working mixture.

$$T_1 = 380 \left( \frac{4}{0.87} \right)^{0.26} = 560 \text{ deg. abs.}$$

$$T_1' = 1200 \left( \frac{18}{3.3} \right)^{0.26} = 1790 \text{ deg. abs., and so on.}$$

Points for the temperature curve may be determined graphically from the general relation:

$$PV = R_1' T.$$

Where  $R_1'$  refers to the whole mass of the gases and not to 1 kg.

From point  $a$  (Fig. 2) draw the lines  $ac_1 \parallel OV$  and from point  $a'$  line  $a'O$  to the intersection with line  $ac_1$  at point  $K$ . It will be found that  $K'O = R_1'$ , since

$$K'O = Oa_1 \frac{KK'}{a_1 a'} = \frac{V p a}{T a} = \frac{1431.25 \times 0.87}{380 \times 6.35} = 52 \text{ min.}$$

where  $6.35:1 = \frac{V_h}{\text{stroke}} = \frac{1145}{180}$  is a scale for diag. (Fig. 2.)

Lay off on the vertical line  $K'g$  a distance  $R_1' = 52$  min. and from the point  $h$  of intersection with line  $ch$

draw the line  $hO$ . The intersection of  $hO$  with  $mx'$  determines point  $C'$ , and so on.

In the same way we determine  $R_1'$ .

According to equation (10):

$$R_1' = R_1' = 52 \times 1.1 = 58 \text{ min.}$$

$$\text{Also, } l'O = \frac{l'z'' \times mO}{mx'} = \frac{p_s V_o}{T_s} = \frac{29 \times 286.25}{2150 \times 6.35} = 58 \text{ mm.}$$

Lay off the length  $l'z''$  on line  $R_1'$  and line  $Oz''$ , determine point  $z' = T_s = 2150$  deg. abs. or draw the line  $Oz'$  until it intersects with line  $mx'$ . Point  $z''$  determines the explosion pressure  $p_s = 29$  at. Point  $S, S'$ , the intersection of line  $Oz''-Ot$  with the expansion curve  $ez$ , gives the necessary correction for delayed combustion in the theoretical indicator diagram for maximum pressure and temperature.

The above-mentioned corrections have practically no influence on the area of diagram, the character of the expansion line and the fuel consumption. The result can be made still more valuable if the calculations are carried through for different air-gasoline ratios and different heating values of the fuel.

It seems apropos to explain the derivation of the fuel consumption equation (42).

The indicated work of 1 kgmol. or 1 kg. of fuel per I. H. P. hour is

$$N_1' = \frac{p_1' \times V_1 \times 1000}{75 \times 60 \times 60} = \frac{P_1' \times V_1}{27}$$

$$\frac{28.89}{1.293} = 22.33 \text{ cu. m.}$$

where  $V_1$  is the piston displacement for 1 kgmol. or 1 kg. of fuel in cu. m.

$p_1'$ , the corrected theoretical mean indicator pressure (equals 40, 41).

To find the value of  $V_1$  we proceed as follows:

The volume of 1 kgmol. of air at  $p_o, T_o$  is 28.89 being the weight of 1 kgmol. of air and 1.293 being the weight of 1 cu. m. of air in kg. at 0° and 760 mm.

(22.33 cu. m. is the volume of 1 kgmol. of all gases.)

The volume of 1 kgmol. of gas at  $p_o, T_o$  is

$$\frac{22.33 \times 1.0334 \times T_o}{p_o \times 273} = 0.0846 \frac{T_o}{p_o} \text{ cu. m.}$$

1.0334 kg. per sq. cm. being the atmospheric pressure at 760 mm.

The volume of working mixture at  $p_o T_o$  (for 1 kgmol. or 1 kg. of fuel) divided by the volumetric efficiency  $\eta_v$  gives

$$V_1 = 0.0846 \frac{T_o}{p_o} \frac{A}{28.89 \times \eta_v} \text{ for 1 kg. of fuel}$$

where  $A$  is the ratio of air to gasoline (16).

Substituting the value of  $V_1$  in the expression for  $N_1$

and taking  $\frac{1}{N_1}$  we get the fuel consumption in kgmol. or in kilograms per indicated horsepower-hour—

$$N_1 = \frac{p_1' \times 0.0846 \times T_o \times A}{27 \times p_o \times 28.89 \times \eta_v}$$

Fuel consumption per indicated horsepower-hour:

$$F = \frac{1}{N_1} = 9220 \frac{p_o \times \eta_v}{T_o \times p_1' \times A} \quad (42)$$

$$\text{or } F = \frac{9220 \times 0.82}{290 \times 7 \times 16} \dots \text{ and so on.}$$

*Machine gun mounting on a turret surrounding the observer's cockpit*

## The Bristol Two-Seater Fighter

ONE of the fastest machines used by the British air force is the Bristol fighter, a two-seater tractor biplane. It has been fitted with a number of different engines, including the 190-hp. Rolls-Royce, the 150-hp. Hispano-Suiza, the 200-hp. Hispano-Suiza, and the 200-hp. B. H. P. The armament of this machine consists of one synchronized Vickers machine gun, operated by the Constantinesco interrupter gear, and one Lewis gun, on a ring mounting. For the Vickers 88 rounds of ammunition are carried, and for the Lewis 7 drums. This machine has a total weight of 2779 lb. and an endurance of 3 hours' flight at 10,000 ft., including the

climb. Its ceiling is 20,000 ft. At the ground level the speed is 119 m.p.h., and at 10,000 ft. 113 m.p.h., while the time required to reach an altitude of 10,000 ft. is 13 min.

The Bristol Fighter has a span of 39 ft. 3 in., an overall length of 25 ft. 9½ in., and a height 9 ft. 4 in. The machine was originated by the British & Colonial Aviation Co., and made its first appearance in January, 1917. It is still being manufactured.

One of the accompanying illustrations shows a close-up view of the observer's cockpit and machine-gun mounting.

# The Pfalz Single-Seater Fighter\*

## PART IV

### Arrangement of Wings and Bracing, and Method of Attachment to Body

FUNDAMENTALLY the Pfalz single-seater belongs to the type frequently termed by the Germans a one-and-a-half-plane; that is to say, it is a machine having a larger top plane and a smaller bottom plane. The type was originated by the French Nieuport firm, and the first machine of this type, if not actually making its appearance, was at any rate contemplated, before the outbreak of war. Since then, although comparatively recently, the enemy has copied the type fairly extensively, chiefly in the Albatross single-seaters and in the make at present under review. Aerodynamically this arrangement of the planes is of advantage on account of the fact that in a biplane the lower plane is the less efficient, and that therefore the more of the total surface is formed by the top plane the better the overall efficiency. Practically also certain advantages attend the arrangement. The effect of the smaller lower chord is twofold. The gap between the planes need not be so great as in the case of a biplane having both planes of the same chord, and for a given fuselage depth the top plane may therefore be placed at a smaller height above the top of the body, resulting in a better view forward. Again the smaller bottom chord does not obstruct the view downward to the same extent as does a plane of larger chord. Thus the "one-and-a-half-plane" forms a good compromise between the lighter structure of a biplane and the good visibility of the "parasol" monoplane, which latter is probably unsurpassed as a fighter as far as obstructing the view in all directions to the smallest extent is concerned.

In the design of its wing structure the Pfalz shows several interesting features. The outward slope of the

struts connecting the body with the top plane was originated, we believe, by the Sopwiths in their "one-and-a-half strutter," while the Vee form inter-plane struts are typically Nieuport. Constructionally, however, the Pfalz is a good deal different in both these features. The Vee struts are not strictly speaking placed in the form of a letter V, as they do not quite meet in a point on the lower plane, which has two spars instead of the single spar employed in the original Nieuport. The object of having two spars is evidently to provide a more rigid structure better capable of resisting the twisting moment due to the travel of the center of pressure. Owing to the fact that the inter-plane struts do not come to a point, incidence wires should be employed, but in their stead the struts are so built up as to form the bottom of a solid U which lends to the lower ends of the struts the rigidity usually provided by incidence wires. The same applies more or less to the body struts, which, as was shown in the illustrations published in our issue of Sept. 5, are in the form of an inverted, flattened U with its cross member adjoining the upper plane. Here, again, the construction of the struts has been designed to perform the function of incidence wires. While on the subject of these struts,

Attachment of center section struts to body on the Pfalz

General arrangement of the wings of the Pfalz

Upper and lower wing sections of the Pfalz, with sections of the wing spars

Quick-release attachment of lower wing spars to fixed wing roots of the Pfalz

Wiring diagram of the Pfalz single-seater. The bracing of the center section struts does not run across the top of the body

attention may be drawn to a somewhat unusual arrangement of the transverse bracing cables. Generally these run from port top rail to top of starboard body struts and *vice versa*. In the Pfalz, however, this arrangement has been discarded and the arrangement indicated in the bracing diagram herewith substituted. The cross wiring does not, it will be seen, run over the top of the body at all. Instead the cables from the upper ends of the struts on one side run to the root of the bottom plane on the same side. The body struts pivot around their attachment to the body, and any lateral displacement of the top plane would therefore result in a raising of one side or the other with a consequent tightening of the corresponding cables. From a practical point of view this arrangement of the cables would appear to possess considerable merits. The crossing of the cables above the body generally necessitates piercing of the top covering, which in most machines is raised considerably above the top longerons, to which the lower ends of the cables are usually anchored. These wires are therefore as a rule difficult to get at, and from a rigger's point of view at any rate the Pfalz arrangement appears preferable. Then again wires crossing above the body frequently interfere with the placing of the machine guns, or with the sighting tube and other accessories. Aerodynamically, it is true, the Pfalz ar-

range is at some slight disadvantage, inasmuch as the length of cables exposed to the air is greater than in the case of cables crossing above the body. When, however, as in the Pfalz, the struts are designed to do away with incidence wires the total length of cables is probably no greater; so one is inclined to consider the arrangement worth while.

The general arrangement of the Pfalz wings is shown in an accompanying illustration. Ailerons are fitted to

the top plane only, as is almost universal practice in Germany. They are hinged to a false spar, and have their crank levers working in slots in the plane, another feature characteristic of enemy machines. This part of the wing is reinforced extensively by the use of three-ply wood. As shown in the drawing, the petrol service tank is built into the top plane, as is also the radiator, which is provided with a shutter that can, owing to the low placing of the top plane, be operated direct from the pilot's seat, a handle projecting aft from the radiator being provided for this purpose. This central portion of the top plane is also reinforced by a covering of three-ply.

The two wing sections of the Pfalz are shown herewith. The lower section is not, it will be observed, an exact geometrical reduction of the upper one, the trailing portion of its lower surface being more in the nature of a reversed curvature than is the case with the top section. The difference does not, however, appear to be great. The maximum camber of the sections appears to be smaller than one usually finds on German machines. At the same time the camber is very considerable for a machine intended for fast flying, and it is possible that the wing section is partly responsible for the inferior performance of the Pfalz.

The wing spars of both planes are of the box form, although not, as indicated in the sections, made up in the usual way of two channel sections joined by a hardwood tongue and grooves. The flanges of the spars are of spruce, and of the section shown in the illustration. Front and rear faces of the spars are formed by plies of wood made up of two thin outer layers of three-ply with a thicker layer of spruce in between them. At points where the spars are pierced by bolts for the attachment of inter-plane struts or internal compression tubes, the space between top and bottom flanges is filled up solid by packing pieces. The attachment of the spar webs to the

(Continued on page 565)

## Two Things That Women Didn't Do Before the War

THESE photographs, taken in the Packard plant, show how women have been trained as welders in the Liberty Engine Department. Experience has shown that while welding is an operation which women learn more slowly than they do most others, they nevertheless acquire gradually a high degree of skill, and are, as a class, more careful with their work than men.

At the left are shown new women employees at the Packard plant being trained for places in the body trimming department. Training and production go along together.

## Tractor Sales Representatives

A RECENT investigation of the tractor sales situation in the Middle West disclosed the fact that the majority of tractors are being sold by automobile dealers. Many of these in the past were implement dealers, but when automobile development made possible the sale of large numbers of these vehicles among farmers these dealers recognized the opportunity and took advantage of it with the results that now their automobile business greatly exceeds their implement business. The advent of the automobile in the agricultural sections put the implement trade through a process of natural selection. The wide-awake, enterprising, progressive implement men became automobile dealers, while the slow, conservative element in the implement trade stuck to its old line and to the somewhat out-of-date service methods peculiar to it.

When, later on, the farm tractor became a practical proposition it was an easy guess which of the two classes of dealers would be first to take up its

sale. The automobile dealer not only was most eager to embrace the opportunity offered, but was most sought after by the tractor manufacturers, because of his familiarity with the service methods current in the automobile business and his ability to render similar service to tractor customers.

So much for conditions in the Middle West. In the Eastern territory tractor sales development has presented a somewhat different aspect, owing to the predominance of our city population. Passenger cars have been sold mainly in the cities, and until recently our metropolitan dealers did not think of taking on more "essential" lines, to use a term made familiar by war conditions. Motor trucks, too, have been sold chiefly in the large cities, but, with a certain number of exceptions, truck sales agencies have been kept separate from passenger car agencies. The average metropolitan truck dealer has probably done as good a business during the past year as during any previous period and has not been looking for new lines. Business in passenger cars has fallen off greatly, but neither his location nor his previous business experience fit the metropolitan automobile dealer specially as a tractor sales representative.

These remarks are not made to disparage those people who have established general distributing agencies in New York from which to organize local agencies. But the opportunities for direct sales from a city branch are very slight, as experience in the West, where most tractors have been sold so far, has shown that farmers almost invariably buy from their nearest dealer, no doubt because from him they can expect the promptest service. During the period of the war we may materially expect to see certain abnormal developments, but after the return of normal peace times we do not expect to see any tractor salesrooms along Broadway.

Tractor manufacturers who cater particularly to the Eastern trade have found that agents for popular-priced cars in country towns make the most successful tractor dealers. They are close to the farmer, they have the necessary service facilities, and since the curtailment of passenger car production they have been looking for new lines.

## The Employer's Responsibility

THE fact that the Government has organized the United States Employment Service does not by any means relieve the employer of the very great responsibility of putting his employment practices on a scientific basis. His local employment board will not consider it a recommendation for any employee to learn of him that he still adheres to the antiquated hiring and firing method of handling his labor problems. In expecting the co-operation of the Government employment agencies, he must know that he is expected to do his utmost to keep turnover at the lowest possible point and to maintain proper working conditions. It has been demonstrated repeatedly that the surest way to secure these results is to install a central employment department equipped for the prompt discovery and analysis of unfavorable working conditions.

## \$6,000,000,000—The Civilian Soldier's Task

**T**HERE is no higher spirit in man than that of self sacrifice.

It is a sublime gift bestowed by the Creator on man.

The time has arrived, as never before in our lives, when we can show this spirit of self sacrifice.

The Fourth Liberty Loan offers this opportunity.

Each manufacturer must consider it his especial opportunity. It is akin to the tide of opportunity that Shakespeare speaks of which comes in the life of every man and which if taken advantage of leads on to fortune, but if neglected lands us in shallow shoals.

The three former Liberty Loans have been mere training schools for this grand and glorious opportunity. This is the opportunity supreme and to many it will be the test supreme.

Six billions is a good round sum, but a sum that is as nothing when the object for which it goes is considered.

In the past Liberty Loan drives we have purchased bonds, but that is only passing credit to us. They have been good investments. We did not have to purchase until the purchase pinched and pinched hard, but in this six billion drive there is going to be some pinching.

There may be pinching but there must be no flinching

No civilian soldier at home living in his house of comfort, living amidst his friends as he has done for years, using his automobile six days in the week, going to the theatre or movies as he has been in the habit of going, and in general eating more sanely for his own benefit, can even think of flinching.

These six billions are needed for those who in khaki are ready without a whimper, without a flinch, without an excuse and with a smile on their faces to make the supreme sacrifice.

They have left the comforts of home behind. They have severed family circles. They have sacrificed good positions. Some of their families have moved from good homes into smaller and more humble ones. Some of their families have moved from front apartments in good streets of our cities into very inferior ones.

They have done theirs, and now it is our turn.

Manufacturers must not only do their duty in this Liberty loan so far as their corporation is concerned, but also so far as every employee is concerned. Wages have increased 80 per cent and living expenses have increased but 60 per cent. Such employees cannot flinch.

Every factory organization should card index every employee.

His capacity to purchase Liberty Bonds should be investigated to the last syllable.

We expect every soldier in France, in Russia, or in any other country where we are fighting, to take his place in the ranks. He must answer the roll call.

At home, every factory employee must answer to the Liberty bond roll call.

Any employee who does not buy should show the reason why.

In a democracy, we cannot have one rule in war time for soldiers and another code of ethics for civilians.

The army in the factories at home must do its duty as faithfully to the very letter as the army at the front or in the training camps.

Every workman who owns a Liberty bond is a better workman for owning it. He becomes a stockholder with Uncle Sam in this country. Every stroke of efficiency comes back to him in dividends.

For the next four weeks it is our duty to civilization to do our utmost to successfully put the six billion loan across.

This is our opportunity.

## Truck Curtailment Protest

Many Makers Call Plan Unjust  
—Would Benefit Those Having War Work

WASHINGTON, Sept. 21—Protests from truck manufacturers regarding the ruling of the War Industries Board, limiting the production of motor trucks during the last 6 months of 1918, to one-third of the total production for the 18 months preceding that period, are still being made. Individual truck makers have in many cases laid their complaints before Washington authorities, and from many sections of the country come representatives giving indications of how the allotment is going to affect them.

So far as a great many makers are concerned the situation is very serious. Take the case of a manufacturer who has been allowed approximately 1200 trucks from July 1 to December 31, and who has already shipped over 900. This means that he cannot possibly retain his organization during the remaining months of the year on a 300 truck program. Such a manufacturer has pretty nearly his complete stock on hand, and while it has been suggested that he could hold the stock and not use it until after January 1, it must not be forgotten that the stock has to be paid for. This introduces a financing problem which is not a very easy one.

Many similar examples could be cited, which would seem to indicate that the allotment for the truck companies for the 6 months is such that the organization could hardly be kept intact during the remainder of the year. The overhead would be so heavy as to make this scarcely possible.

This reduction program, in view of the fact that motor trucks have been declared essential, seems certain to work special injury to truck companies not engaged and filled up on Government truck work. These companies have been preparing for the commercial demands of the country, which the companies going 100 per cent on Government work have not been able to take care of. The ruling seems to play strongly into the hands of these truck makers, as it can only be interpreted as cutting down the commercial field of the manufacturer who has not the Government work. In other words, while one group of truck makers is engaged on profitable war work, rulings are made to restrict the business of those who are taking care of the commercial field. With trucks classed in the essential column, it is difficult to see the underlying reason for this action.

C. C. Hanch, chief of the Automotive Products Section, stated yesterday that he has been given latitude by the War Industries Board, which will allow him to enlarge or decrease the apportionments for production for truck makers during the last half of 1918. By this means he expects to give aid to the truck makers who have only been in business a short time, and also to make reasonable adjustments to those manufacturers who believe that their apportionments under the original ruling of one-third of the last 18 months' business would be unfair. Truck manufacturers are hoping that through Mr. Hanch's efforts a reasonable adjustment can be effected.

A number of unjust results are reported by the truck makers who object to the ruling. They cite the instance of the manufacturer who has only been in the truck making business for the last year or the last year and a half, and who, under the ruling, would be allowed only a very small amount of trucks at this time. Again, there is a manufacturer who was unable to secure his materials because of the many difficulties during the last winter, and consequently had to cut down his production. He now has the materials after much expenditure of effort and money, and also has the orders, but owing to the ruling, is limited in his output.

This ruling came as a great surprise to the general industry. Following all of the previous declarations of the War Industries Board affirming the essentialness of the motor truck, it has been difficult to understand the exact reason for this latest move. Inquiry at the Automotive Section of the Board developed two possible reasons: (1) It was said that the motor truck is not, outside of war work, declared essential by the War Industries Board.

(2) It was stated that patriotic manufacturers engaged in truck work for the Government should be protected during the war against manufacturers building trucks for commercial purposes.

The latter reason scarcely deserves consideration. It is hardly believed that this was stated seriously. It is well known that all of the truck manufacturers have been anxious to secure Government work, and have patriotically, and for excellent business reasons, endeavored to secure war contracts. Also, it is a question whether it is within the function of the War Industries Board to control general industrial and commercial business for the sole reason of "protecting" war manufacturers.

The first assertion that motor trucks for commercial or industrial purposes had not been declared essential by the War Industries Board is a surprise. As early as June 26 the War Industries Board stated in a letter signed by the Vice Chairman of the Priorities Committee:

"We beg to advise that the Priorities Committee views the motor truck in most instances as being a helpful medium, particularly at this time, and are not disposed to hamper the production of same."

Later, on Aug. 8, the War Industries Board issued Circular No. 11, stating:

"Careful consideration has been given to the several problems, and a decision reached that motor trucks, in so far as they are used directly or indirectly for war purposes, are

## Glover Heads Motor Division

Has Charge of Procurement of Motorized Vehicles—Three Separate Branches

WASHINGTON, Sept. 25—Organization of the Motors Division of the Quartermaster Corps, which has charge of motor propelled vehicles, has been completed. This division procures the motorized vehicles for the Motor Transport Corps, which has charge of maintenance, operation and engineering.

Colonel Fred Glover of the Quartermaster Corps, formerly general manager of the Emerson-Brantingham Agricultural Implement Manufacturers, Rockford, Ill., is the chief of the Motors Division. Major Guy Hutchinson, formerly an automobile dealer in New York City, is the executive officer. Colonel E. S. George is the assistant chief of the division. Major A. H. Zacharias, who several years ago was connected with a pressed steel company, is the production assistant. Major C. S. Dahlquist, formerly of the Timken Detroit Axle Co., is the technical assistant.

The division comprises three branches, procurement, administrative and district offices. The procurement branch is organized in sections as shown below.

Captain Finkenstadt, given herewith, was formerly assistant to Christian Girl, president of the Standard Parts Co., assistant to Mr. Girl when he was in charge of Army truck production, and later was in charge of B truck production, following Mr. Girl's resignation. By this new organization he has been placed assistant to Major A. B. Browne. Mr. Morrison was connected with the Highland Body Co. Mr. Hess was formerly with the Cleveland Motorcycle Co. All of these men named here together with their connections were formerly connected with the Motor Transport Service under Christian Girl.

The administrative branch is under Captain S. P. Dean and includes: Office control, under Captain A. D. Stansell; personnel, W. A. Dickey; clearances, D. G. Blair; finance and statistics, A. G. Drefs; trucks, Captain H. M. Lowy.

## Trucks Hold Destiny of Industry

### Highways Transport Committee Meeting Emphasizes Importance of Highway Haulage

WASHINGTON, Sept. 21—"The world is never more than 60 days ahead of famine between harvests, and great starvation areas will develop in Europe.

"Fifty per cent of our perishables raised on the farms never reach the consumers. We lost 40 to 60 per cent of our potatoes yearly. The producers are too remote from the markets."—Herbert Hoover.

"Following the war we will develop a nation of small farming communities on new land open or reclaimed, and cultivated largely by America's war veterans. These centers will all be united by motor rural express vehicles operated over our highways. The Government intends to furnish farming opportunities for the soldiers, and we must have highways to complete such a program."—Franklin K. Lane, Secretary of the Interior.

#### A Trinity of Usefulness

"Our means of transportation, waterway, railway and highway are not hostile but a trinity of usefulness, but you may put six tracks on each side of the Hudson and fill it with steamships, and unless you put the inland farmer in touch with the docks and the depots neither will be useful to him."—William C. Redfield, Secretary of Commerce.

These were some of the high thoughts that are to come about because of the war and a more efficient control of highways transportation, and were given vent to at the meeting of the Highways Transport Committee held here last week, when the regional chairmen of the committee spent three days going over the work and listening to various addresses. Chairman Roy D. Chapin met with the eleven regional chairmen present and laid broad plans for a pushing of the work.

One of the possible outcomes of the meeting is action leading toward a more positive system of gasoline economy by motor vehicles. Up to date the gasoline economy program has been one of curtailment, a negative program, so to speak. The possibilities of a positive program of curtailment were outlined. This will consist of keeping motor vehicles in better operating condition so that great quantities of gasoline will be saved. Some of the regional chairmen are already arranging plans whereby

they will carry on a campaign along this line through their entire area.

Herbert Hoover pledged his entire food administration back of the highway movement. "Europe is exhausting the candle of present and future resources at both ends," said Mr. Hoover, "and for 10 years after peace comes the productivity of the United States will be called upon to aid the Allies and the millions of people exploited by Germany. One of the results of a perfected highways use would be to cut down the waste of perishable foods. Besides stopping this terrific waste a highly developed rural express would work to establish lower prices. Europe has an intimate system of railway lines and canals to transport these products to nearby markets. Where the rural express has been developed in this country it has operated to these ends. I should say that the failure of public markets in this country is due to the tremendous loss of perishables shipped from remote distances. A network of rural deliveries will provide the economic basis for a successful public market.

"A further effect would be to bring into productive activity the large potential of labor now on the farm but not actively producing. Wherever mechanical transports can be employed there will be a decrease of work animals necessary. Our 25,000,000 to 40,000,000 work animals are eating the crops of an acreage that, planted to food, would sustain 40,000,000 more people."

Joseph D. Baker, of the Priorities Division of the War Industries Board, discussed the feasibility of federal license of motor car and truck drivers to conserve fuel, steel, lubricants and manpower employed in service stations. It will be recalled that earlier issues of AUTOMOTIVE INDUSTRIES predicted a probable federal license plan of this sort operated by the Priorities Division. It has been rumored for some time.

Reports made by the regional chairmen show tonnage moved over the highways increasing at a tremendous rate. In some States as much as four hundred per cent increase over last year being shown. The Cleveland-Akron-Canton area reported sixty-

(Continued on page 558)

#### Tom Jones Killed in Seaplane Accident

NEW YORK, Sept. 25—Tom Jones, formerly connected with J. B. Crockett & Co., exporters, and previously advertising manager of the Empire Automobile Co., who last year traveled through the Orient for the United States Government making investigations on automobile conditions, was killed yesterday at Pensacola, Fla., in a seaplane accident.

## Cut Iron and Steel for Tractors

### War Industries Board Limits Quantity for Next Year to 75% Used Last Year

CHICAGO, Sept. 21.—The quantity of pig iron and steel which manufacturers of tractors and other farm implements may use in the year commencing Oct. 1, 1918, and ending Oct. 1, 1919, has been limited to 75 per cent of the quantity used in the year ending Oct. 1, 1918. This action has been taken by the War Industries Board following conferences which were held last week in Washington between the War Service Committee of manufacturers of agricultural implements and farm operating equipment and Priorities Division of the War Industries Board.

Although this limitation of iron and steel will mean curtailment in the production of tractors to some extent, it is not possible to state at the present just how much the curtailment will amount to. The War Industries Board has not specifically limited the production of tractors and other implements to 75 per cent of the production during the year ending Oct. 1, 1918; instead it has merely limited the quantity of iron and steel which manufacturers of these implements may use. It is estimated that this action will release 500,000 tons of iron and steel.

#### Expect Relief

In its circular to the trade, the Farm Implements Committee, of which C. S. Brantingham is chairman, states that "possibly some relief may be obtained by substantial reduction of inventories by the end of the year Oct. 1, 1919," and adds "that it becomes the obligation of the manufacturer to adjust himself in the way that will serve his trade and the farmer best out of the materials allotted him."

The War Industries Board urges that a full assortment and stock of repair parts be supplied to the farmer as a means to assist and encourage him to continue to use the equipment he now owns.

#### Streator to Quit

OTTAWA, ILL., Sept. 20—A decree of foreclosure and sale has been entered against the Streator Motor Car Co., formerly of Streator, Ill. The sale is set for Thursday, Oct. 10, at Ottawa, and will involve real estate in Streator.

## May Be Less Gasoline in 1919

### War Demands During Coming Months May Prevent Accumulation of Surplus

Washington, Sept. 21.—The gasoline situation is serious not so much because of a present shortage as because of shortages that will occur early next year. There is a serious discrepancy between gasoline production and consumption at present, but this is not critical, as the motoring season is practically at an end and the stocks of gasoline will from this time on increase. However, it is probable that heavy drafts on the stocks of gasoline for war purposes both at home and abroad, during the winter and the spring, will prevent the usual large stocks that accumulate through the winter and will thus create a serious gasoline shortage for 1919. For this reason voluntary conservation must be practised constantly and every step must be taken not only to conserve gasoline but to increase the future supply and the supply of crude oil. These are the salient points of a report submitted by Van H. Manning, Director of the Bureau of Mines, Department of Interior, to the Senate, as a result of a resolution presented by Senator Lodge.

Figures were presented in the report showing that the monthly consumption, including exports of gasoline for August, amounted to 9,500,000 barrels as compared with a monthly production of 8,000,000 barrels, creating a shortage of 1,500,000 barrels per month comparing the demand with the production. Following is the major part of Director Manning's statement:

These figures, said Director Manning, show gasoline consumption to be seasonal, with the greatest demand in the summer, with the demand decreasing in the winter as the storage stocks increase. During the summer of 1917 storage was at a minimum and reached its maximum in March, 1918. At present gasoline stocks are falling off because the entire output of the refineries is not enough to meet the increasing demand. August is expected to show the same demand as July so that the stocks at the end of August, 1918, will probably be between 6,000,000 and 7,000,000 bbls. September will witness the culmination of that period of greatest consumption and close the heavy drafts on stocks unless exports increase at a greater rate than is now expected.

"In normal times," continues the report, "such a discrepancy between production and consumption during the summer months would cause no undue consternation for sufficient gasoline would be stored during the winter months to more than overbalance the heavy summer demand. At present, however, conditions are abnormal and it is difficult to forecast the future. The domestic demand for gasoline during the coming winter will probably be reduced by a falling off in automobile production and the neces-

sity for economy among the people. On the other hand our war demand for gasoline both at home and abroad will probably be tremendous, especially with the advent of spring, so that the situation is really serious but not so much because of present shortage as because of the forthcoming shortage of next year.

"We are not now producing enough crude oil to supply refineries, gasoline stocks have been reduced to a two weeks' or three weeks' supply, and although the present situation has been well taken care of by the Fuel Administration we are facing a tremendous demand next spring and a demand as inflexible as it is great for we must have adequate supplies of gasoline for our own overseas forces and for those of our Allies. The need for conservation is apparent and the American people should voluntarily forego the pleasure of needless automobile touring during these times. Such voluntary conservation may now prevent the necessity of more serious action later. Furthermore, every step should be taken by the people and their representatives not only to conserve our present supply of gasoline but also if possible to increase our future supply and the supply of crude oil from which gasoline is made."

### Licenses for Experimental Flights to Be Submitted to Army and Navy

WASHINGTON, Sept. 21.—Applications for flying licenses to conduct experimental flights must hereafter be submitted to the proper Army and Naval authorities before being filed with the Joint Army and Navy Board on Aeronautic Cognizance, Building D, Sixth and B Streets, Washington, D. C.

Applications should be made either by individuals or airplane companies making new types of navy airplanes to Captain N. E. Irwin, U. S. N., Director Naval Aviation Division, New Navy Building, Washington, D. C., and for flying army aircraft to the Technical Section, Division of Military Aeronautics, Dayton.

## Gasoline Stock Down 68,531,749 Gal.

### July's Production Figures Satisfactory, But Stock Low at End of Month

Production			
	July, 1918	June, 1918	
Crude oil (bbl.)	29,170,718	28,140,479	
Gasoline (gal.)	332,022,095	315,023,445	
Stocks on Hand			
	July 31, 1918	June 30, 1918	
Crude oil (bbl.)	14,026,525	11,956,151	
Oils purchased to be re-run (bbl.)	1,548,971	932,561	
Gasoline (gal.)	349,928,604	418,440,353	
Kerosene (gal.)	432,807,129	426,285,676	
Gas and fuel (gal.)	519,012,839	550,704,759	
Lube. gal.)	136,460,207	158,316,257	
Wax (lb.)	176,539,564	169,424,428	
Coke (ton)	17,943	17,148	
Asphalt (ton)	92,597	97,631	
Miscellaneous (gal.)	450,086,589	273,877,024	

WASHINGTON, Sept. 23.—During July, 1918, the daily production of gasoline was 10,710,390 gal. against a daily average for the previous month of 10,500,781 gal. The improvement is slightly better than indicated by the figures as July had 31 days compared with 30 in June.

The stock of gasoline on hand at the end of July shows a decrease of 68,531,749 gal. when compared with the end of June stock and is no less than 110,708,875 gal. below the stock at the end of May. Obviously some reduction is expected during the summer months, and doubtless the temporary stoppage of the use of passenger cars on Sundays will help to bring back the stock figures to normal.

The crude oil position is slightly better, both as regards production and stock,

### Production and Consumption of Gasoline

Increase in crude oil consumption by refineries:	
Daily average 1917.....	863,374 bbl.
Daily average first 7 months 1918.....	874,964 bbl.
Increase.....	11,590 bbl.
Daily average increase for July, 1918.....	940,991 bbl.
Increase over July, 1917.....	77,617 bbl.

The following tabulation shows the changes in stocks of the principal refined products except gasoline from Jan. 1, 1918, to Aug. 1, 1918:

Kerosene.....	127,744 bbl. decrease
Gas and fuel oils.....	737,882 bbl. decrease
Lubricating oils.....	171,878 bbl. decrease
Paraffine wax.....	21,790,190 lb. increase

The following tabulations show the approximate production, consumption and stocks of gasoline for the first 8 months of 1918:

Months	(b) Production, Bbl.	(c) Stocks at End of Month, Bbl.	(d) Decrease or Increase for Month, Bbl.	(e) Average Daily Increase or Decrease in Stocks, Bbl.	(f) Total Con- sumption, Including Exports
December, 1917.....	9,815,000	11,160,000	+	1,345,000	4,235,000
January, 1918.....	5,580,000	12,350,000	+	1,190,000	4,180,000
February.....	5,370,000	12,550,000	+	200,000	6,210,000
March.....	6,410,000	12,120,000	—	430,000	7,420,000
April.....	6,990,000	10,950,000	—	1,020,000	8,620,000
May.....	7,800,000	9,960,000	—	990,000	8,490,000
June.....	7,500,000	8,330,000	—	1,630,000	9,530,000
July.....	7,900,000	6,830,000	—	1,500,000	9,500,000
August.....	8,000,000				

The month of August, as shown in the above figures, was an estimate as the figures from the refineries are not yet available.

Column (d) shows an excess of production over consumption or in other words amounts that had to be taken from storage to meet the demand.

Column (e) shows that during July the average daily gasoline shortage was 52,600 bbl.

and there is a substantial improvement in the item of re-run oil. This is given separately for the reason that it represents crude or distillate which has been included in the regular crude oil production figures at some prior date.

Owing to the abnormal demands of the naval and merchant marine, the largest item in the stock list is that covering fuel oil. During July the average daily production of this was no less than 21,239,990 gal.—nearly double that of gasoline.

#### Packard Has Graduated 1259 Women

DETROIT, Sept. 20—The Packard Motor Car Co. has graduated 1259 women and girls from its training school which was established last spring. Approximately two-thirds of the Packard women employees, of which there are more than 1000, were trained in this school. The present school enrollment is 250.

#### Powell Buys Omaha Auto Supply

OMAHA, Sept. 23—The Powell Supply Co., of which the president is Clark G. Powell, has purchased the entire stock of the Omaha Auto Supply Co., a concern which has been in existence for seven years. The stock is said to be worth \$50,000. Part of the Omaha organization goes with Powell, including Manager Wilson.

#### Canada Wants Gasoline Cards

MONTREAL, Sept. 23—The Montreal Automobile Association, through Secretary Thomas C. Kirby, has petitioned the authorities at Ottawa for the issuance of gasoline cards to our owners instead of the establishment of regulations which forbid the use of cars on Sunday.

## Gasoline Men to Be Licensed

### Oil and Gasoline Makers and Dealers Having Business Over \$100,000 Affected

WASHINGTON, Sept. 21—Importers, manufacturers, distributors and transporters of crude oil, fuel oil, gas oil, kerosene or gasoline whose annual businesses exceeds \$100,000 will be required to operate under a license on and after Oct. 1, 1918, according to a proclamation issued to-day by President Wilson.

The licenses can be secured from the United States Fuel Administration, Oil Division, Washington, D. C. Special blank forms will be provided by the Fuel Administration for that purpose. Holders of existing licenses already issued by the United States Fuel Administration are not required to secure new licenses.

The proclamation issued by the President is under the authority of the Congressional Act, "to provide further for the national defense by encouraging the production, conserving the supply, and control the distribution of food products and fuel," which was approved by the President, Aug. 10, 1917.

Any individual, firm, corporation or association which continues to carry on a business or importing, manufacturing or trading in crude oil or its products or natural gas, and whose business exceeds \$100,000 yearly, will be liable to penalties prescribed by this act.

#### Employers Should Help Draft Boards

WASHINGTON, Sept. 21—Employers are called upon by the Provost Marshal General of the War Department to assist

the Local Boards and District Boards in making decisions on industrial exemptions under the new draft. In the first draft of 1917 out of more than 3,000,000 registrants called only 140,000 filed occupational claims or 4.7 per cent. Ninety-five per cent of all registrants raised no question of such deferment. Under the next draft it is expected that conditions will be considerably reversed, and that numerous occupational claims will be made.

#### New Army Purchasing Department Appointments

WASHINGTON, Sept. 20—Under the reorganization of the General Staff, Brigadier General Hugh S. Johnson and Gerard Swope have been appointed assistants to Major General George W. Goethals, Director of Purchase, Storage and Traffic.

The Quartermaster General of the Army is made Director of Purchase and Storage and will be responsible for and have authority over storage, distribution and issue within the United States of all supplies for the Army. Colonel William H. Rose of the Corps of Engineers is designated to act under him as Director of Purchase, while Colonel F. B. Wells will act as Director of Storage, with L. M. Bicolson as his assistant.

#### Skilled Men Wanted for War Department

WASHINGTON, Sept. 19—Manufacturers and business men have been requested to co-operate with the General Staff of the War Department to aid in securing skilled office men for War Department work. There is a pressing need for men who have demonstrated their qualifications and ability in statistical work, factory production, accountancy, purchasing, merchandising and warehousing.

## British Organize Industrial Research

Four Industries Now Have Associations, and Thirty More Will Soon

LONDON, Sept. 10—The establishment of research associations is rapidly increasing among British industries. Four industries have already established such associations and 30 more are now preparing to do so, according to the third annual report of the British Research Department, which was organized recently by the Government for the purpose of encouraging research and assisting the scientific investigation of industrial problems.

The industries which now have their research associations are the photographic, scientific instrument making, Portland cement and woolen and worsted industries. There is abundant evidence that the movement is to receive the unqualified support of all industries, as the need for organized research in connection with industries is being increasingly realized. The supply of research workers, however, may cause a serious setback if it cannot be expanded rapidly to meet increasing demands.

The formation of an industrial fatigue research board, which was accomplished with the help of the medical research committee, is one of the most interesting developments of the past year. The function of this board is to consider and investigate the relation of the hours of labor to other working conditions, and their effect on production.

### Privy Council's Policy

The report of the research department was preceded by a supplementary report of the committee of the Privy Council for Scientific and Industrial Research. In this supplementary report the Privy Council stated its policy and said:

"The department has found in the course of its conversations with leading manufacturers that there is sometimes a certain hesitancy to establish relationship with the Government for the purpose of research because of fear that the department will interfere in the work of the new association, and will use its powers in such a way as to prevent the results of research from reaching the firms which have subscribed to its cost, or to give the results to competing firms which have not joined or have left the association."

The council points out that such a result would be fatal to the success of the scheme, and that it is the intention to permit the associations to manage their own affairs, and benefit by their own discoveries. It is thought that the departments can help each association by keeping it in touch with all work.

### War Service Committee for M. A. M. A.

NEW YORK, Sept. 23—At a meeting of the Motor and Accessory Manufacturers' Association Friday it was voted

that President C. W. Stiger appoint a War Service Committee, and that this committee request the War Industries Board for a hearing on the affairs of the parts makers.

The parts makers were included in the industrial committee which operated in Washington at the beginning of the war, but since the committee was reorganized some time ago have not had an official representation for contact with governmental agencies.

The association is sending to members and other parts and equipment makers a statement as to the detail of how the automobile and truck industries are being handled by the War Industries Board, including priority plans and other matters.

### Trucks Hold Destiny of Industry

(Continued from page 555)

one per cent as much freight being moved by motor express now as the railroads are carrying. High development of the returnloads bureau, which insures most economical operation of highways transport, was noted in the State of Connecticut, with Hartford acting as the central bureau. In Cincinnati and Omaha, livestock are being carried to stockyards over the highways in increasing numbers. Rural express has reached its highest efficiency in Maryland, New Jersey, eastern Pennsylvania and southern New York. Arrangements have been made to connect New York State Barge canal ports with the farming communities back from it by rural express.

Edward Chambers, former vice-president of the Santa Fe Railroad, now Director of Traffic in the National Railroad Administration, urged the chairmen to promote the trucking of less-than-carload shipments from the manufacturing centers to communities thirty and forty miles out, and the co-operation of the highways regional chairmen with the railways regional traffic directors, to facilitate the clearing of the terminals in the larger cities. Mr. Chambers announced that in conjunction with the Highways Transport Committee, the Railroad Administration is trying out the store-door delivery system in New York, with hopeful results. If it meets expectations there, it will be extended to other large centers.

The Highways Transport Committee is completing countrywide organization that will number more than 15,000 committeemen, manufacturers, farmers and consumers, all working through contact with the State Councils of Defense and with the committee's regional chairmen.

### Ford Transfers Labor for Ships

DETROIT, Sept. 23—More than 3000 laborers from the Ford Motor Co.'s plant have been transferred to the Ford shipbuilding plant to work on Eagles within the past 3 months. Between fifteen and thirty men are leaving the plant daily to take their places in the ranks of the army or navy. Nearly 6000 employees have left the factory for national service during the last year.

### Franklin to Make Hispano-Suiza Parts

SYRACUSE, Sept. 22—The H. H. Franklin Mfg. Co. has received a contract from the Wright-Martin Aircraft Corp. for parts of Hispano-Suiza engines.

## 8 Hour Day Adopted by Steel Corp.

More Than 275,000 Workers Affected—Midvale Co. Announces Co-operative Plan

NEW YORK, Sept. 24—The eight-hour day has been adopted by the United States Steel Corporation as a basis for calculating wages and working periods for its employees. The new plan will go into effect on Oct. 1. Something more than 275,000 workers in rolling mills, blast furnaces, mines and transportation organizations affiliated with the corporation and operated by it will be affected.

Elbert H. Gary, Chairman of the Board, made the following announcement after a meeting of the directors to-day:

The Finance Committee of the United States Steel Corporation to-day unanimously approved the recommendation of the Chairman and President of the corporation and of the Presidents of the subsidiary companies to adopt the eight-hour basic day, to become effective Oct. 1, 1918. The open-shop plan heretofore in force throughout the works will be continued.

### An Increase of 42 Cents

It is believed, following the lead of the largest unit in the industry, other steel manufacturing concerns will shortly announce the adoption of the eight-hour day.

A day laborer working ten hours under the new schedule will get \$3.36 for eight hours and an additional \$1.26 for the two remaining hours, or \$4.62 all told as against \$4.20 at present.

The increase of 42 cents over the present pay for ten hours is equal to 10 per cent. Applied to the balance available for dividends, the experts calculate that at the current rate of earnings and under the expected Federal taxes, the increase of wages will cause a reduction in the balance of not more than 2 per cent.

### Midvale Adopts Labor Co-operation

The Midvale Steel & Ordnance Co. has invited its employees to co-operate with the officials of the company for the purpose of working out plans for mutual benefit. A committee of employees of the Midvale Co. and the Cambria Steel Co., a subsidiary concern, will meet with a committee consisting of vice-presidents of the Midvale Co. in Philadelphia to arrange details of the plan.

On Monday morning notices were posted throughout the plant of the Midvale Co., signed by President A. C. Dinkey, which read as follows:

We recognize the right of wage earners to bargain collectively with their employers, and we hereby invite all employees to meet with the officers of their respective companies for the purpose of considering and, if practicable, adopting a plan of representation by the employees, which shall be thoroughly democratic and entirely free from interference by the companies, or any official or agent thereof. It is hoped that every employee will respond to this invitation and meet with the officers of the company in the spirit of fair dealing and mutual helpfulness.

## Iron and Steel Price Unchanged

### President Approves Agreement Maintaining Present Figures with Few Exceptions

WASHINGTON, Sept. 24—The President has approved the agreement made by the Price-Fixing Committee of the War Industries Board with representatives of the iron ore, pig iron and steel interests, and the maximum prices now prevailing on these products will be continued in effect for the three months ending Dec. 31, 1918, with the following exceptions:

Lake Superior iron ore base prices delivered to the lower lake ports are increased 25 cents per gross ton, effective Oct. 1, subject to increase or decrease in event that rail or lake rates increase or decrease.

Basic iron base prices have increased to \$33, f.o.b. furnace. The base price on No. 2 foundry iron is increased to \$34, f.o.b. furnace. Standard Bessemer iron is fixed at \$35.20, f.o.b. furnace. These prices are subject to the following changes from previous practice as regards delivery:

(a) Pig iron produced in the Virginia, Tennessee, and Birmingham districts and the scattering districts south of the Ohio and Potomac Rivers, including furnaces at St. Louis, Mo., but not including furnaces bordering on the Ohio River, shall be sold on a f.o.b. Birmingham, Ala., basis.

(b) Pig iron produced in the Eastern district, i.e., from all blast furnaces located east of the Allegheny Mountains and north of the Potomac River, shall be sold on a f.o.b. Pittsburgh basis.

(c) Pig iron from all other producing districts or furnaces shall be sold f.o.b. furnace as heretofore.

No new contracts calling for delivery of any of the above commodities or articles on or after Jan. 1, 1919, are to specify a price unless coupled with a clause making the price subject to revision by any authorized United States Government agency, so that all deliveries after that date shall not exceed the maximum price then in force, although ordered or contracted for in the meantime. It is expected that all manufacturers and producers will observe the maximum prices now fixed.

### Form Marine War Service Committee

WASHINGTON, Sept. 25—W. H. Manass, Director of the War Service Executive Committee of the United States Chamber of Commerce has called a meeting of manufacturers of marine internal combustion engines and accessories, to be held on Sept. 27 at 2 p. m. A War Service Committee of the trade is to be formed.

### N. A. C. C. Meeting Oct. 3

NEW YORK, Sept. 25—Hugh Chalmers, vice-president of the N. A. C. C., will report on the Washington situation as it affects the automobile industry at the regular monthly meeting of the N.

A. C. C., which is to be held at the general offices in New York on Thursday, Oct. 3.

C. C. Hanch, chief of the Automotive Products Section of the War Industries Board, will answer questions relating to priorities, materials, etc. A meeting of the motor truck manufacturers will be held at 2 p. m. George M. Graham, chairman of the National Motor Truck Committee, will speak on "How the Motor Truck Industry Is Affected by Developments in Washington," and will cover such questions as priorities, materials, preference list, classification of employees in the draft, and the best methods of retaining essential men without interfering with the war program.

Other matters to be considered at this meeting are: "Taxes Levied Against Motor Trucks in the New Revenue Bill," "War Orders for Trucks," "Rural Motor Express," "Need for Uniform Laws," "Action on Plan to Standardize Truck Tires," "Work of Highways Transport," and "Increasing Need for Improved Highways to Increase Motor Truck Haulage."

### Range of Travel Governing Factor in Airplane Future

DETROIT, Sept. 21—Range of travel is the greatest problem which must be solved in determining the future of the airplane industry, according to C. F. Kettering, president of Delco and the S. A. E. President Kettering's address was given on the occasion of the first Detroit Section meeting for the year, held at the Hotel Pontchartrain last night.

The topic, "The Future of the Airplane Industry After the War," was of popular interest in this section, as shown by an attendance of 600 local S. A. E. members and their friends. Mr. Kettering largely repeated the address he gave before the Cleveland Section.

A committee was appointed to co-operate with the legislative body in Lansing to frame suitable laws covering headlight glare. This committee was appointed at the request of Governor Sleeper of Michigan, and consists of the following:

W. E. Metzger, president Detroit Automobile Club; Charles E. Godley, engineer of Edmunds & Jones; J. B. Replogle, engineer of the Remy Electric Laboratory; H. J. Platts, engineer of the C. M. Hall Lamp Co.; F. E. Watts, chief engineer of Hupp Motor Car Co.; and J. E. Schipper, chairman Detroit Section, S. A. E., ex-officio member.

### Russel on War Credits Board

WASHINGTON, Sept. 25—Albert W. Russel, formerly president of the Russel Motor Axle Co. and treasurer of the Russel Wheel & Foundry Co. of Detroit, has been appointed a member of the War Credits Board by the Acting Secretary of War, Benedict Crowell, to fill a vacancy caused by the resignation of F. P. Neal.

## Essential Truck Use Defined

### N. A. C. C. Issues List of Industries That May Purchase Vehicles

WASHINGTON, Sept. 23—A list of essential truck users has been compiled by the truck committee of the National Automobile Chamber of Commerce, to be used by makers, distributors and dealers as a guide in the sale of motor trucks.

The list has been approved by the War Industries Board. Motor trucks may be sold to any user included in the lists. They cannot be sold to anyone not engaged in the trades or industries listed without special permit from the War Industries Board.

Truck manufacturers have already filed their pledges to observe these regulations and have exacted similar pledges from their distributors and dealers. Consequently, hereafter the only necessary procedure in making truck sales is to make certain that the prospective buyer is one of the essentials as named by the lists. If his trade or industry is so named no further formality is necessary and the sale can be made. The industries and trades that are essential, besides those named in the War Board's preferential list, are:

Seeds  
Refrigeration.  
Bridge builders.  
Contractors, building, road, paving, sand, gravel, cement, bridge steel and garbage.  
Farm wagon manufacturers.  
Public haulage companies.  
Drayage concerns.  
Transfer companies.  
Casket makers.  
Cemeteries.  
Department stores.  
Elevator makers.  
Hardware manufacturers.  
Heating and ventilating concerns.  
Hotels.  
Hotel supply manufacturers.  
Linoleum manufacturers.  
Plumbers' supplies manufacturers.  
Stove manufacturers.  
Tent and awning manufacturers.  
Tire makers.  
Typewriter manufacturers.  
Warehouses.

### Foreign Missions Members Requested to Return Home

WASHINGTON, D. C., Sept. 26—Members of the foreign military missions, British, French and Italian, who are acting in an advisory capacity to the American army in this country, have been requested by the War Department to return to their own country as soon as convenient and not later than Nov. 1. Only those who are very necessary will be retained temporarily. This request which came in the form of an order from the War Department, created surprise and some feeling on the part of the foreign experts who were aiding our army on such matters as aviation, ordnance, motorized vehicles, etc. The various missions when landing in this country reported to their ambassadors and are surprised because they were not notified that their services were no longer required through the same source.

## To Develop New Oil Lands

Millions of Acres of Federal Territory May Be Available If Bill Passes

WASHINGTON, Sept. 20—There are 6,524,834 acres of land either known to contain oil and gas or believed to contain them, which would be valuable for exploration and development if Senate Bill 2812 is enacted, according to Van H. Manning, Director of Mines. Mr. Manning filed this statement together with other data with the Senate in answer to a resolution requesting his opinion if passing of this bill would alleviate the so-called gasoline shortage. This bill, as told in a previous issue of *AUTOMOTIVE INDUSTRIES*, will allow the Secretary of Interior to grant individuals the right to prospect for oil or gas on Government land.

Director Manning stated in his letter that the enactment of this law will allow for development of vast areas of land in this country, and undoubtedly result in the discovery and development of new oil fields and deposits, will permit the leasing of new land actually proved to contain valuable deposits of oil, permit the further development of existing claims in withdrawn areas which have on them one or more producing wells, and which are equipped with pipe lines and facilities for transportation of oil. He recommends the passing of the bill as highly desirable and believes it will prove an important war measure. Following is Director Manning's letter and that portion of Senate Bill No. 2812 relating directly to the oil and gas land developments:

Sir: In connection with resolution passed by the Senate asking whether the enactment of S. 2812 would help the oil situation, the following is submitted:

Prior to September 27, 1909, public lands in the United States and the Territory of Alaska were subject to exploration, location and purchase under the placer-mining laws of the United States (secs. 2329-2331, R. S., Acts of Feb. 11, 1897, 29 Stat., 536, and Feb. 12, 1903, 32 Stat., 825). Under these laws any citizen of the United States or person who had declared his intention to become such, could go upon the public lands and explore for oil, and upon discovery apply for and receive patent as prescribed in the mining laws. September 27, 1909, the President of the United States withdrew from exploration, location and entry large areas of public lands known or believed to contain valuable deposits of petroleum for the primary purpose of withholding same until Congress could consider legislation designed to secure the exploration for and development of deposits of oil and gas under a leasing law. Similar withdrawals had been made from time to time until at the present there are withdrawn from all exploration, location and entry 6,524,834 acres of land either known to contain oil and gas or believed to possess possibilities thereof. This acreage is not all public lands, as considerable areas within the exterior limits of withdrawals were patented under the various public-land laws prior to dates of withdrawal. There are also withdrawn 132,024 acres of land known to contain valuable deposits of oil shale. The withdrawals cover lands in the States of Arizona, California, Colorado, Louisiana, Montana, North Dakota, Utah and Wyoming. In addition all lands containing deposits of oil in the Territory of Alaska are likewise withdrawn.

Most of the lands so withdrawn are free

from claims and would, if S. 2812 or other legislation providing for their disposition were enacted into law, be subject to exploration and development in accordance with its provisions. A minor portion of the area, comprising valuable proved oil territory was, however, covered by locations made under the mining law prior to withdrawal and the claims so asserted have not been disposed of, but are pending in the Land Department or in the courts. Most of these claims have upon them one or more producing oil wells, but increased production through the drilling of additional wells is practically halted by the withdrawal. The so-called relief provisions of S. 2812 are designed to adjust these controversies and secure the development of the lands.

In my opinion the enactment of a law providing for the development of the oil lands of the United States would (1) open to exploration and development the vast areas of public land in the United States and Alaska now absolutely withdrawn from exploration and development, thereby resulting in the discovery and development of new oil fields and deposits, thus adding to the oil and gas supply of the United States and Alaska; (2) permit of the leasing of lands now withdrawn and actually proved to contain valuable deposits of oil and gas by the existing wells upon the lands or upon adjoining tracts; these fields are principally located in California, Wyoming, Montana and Louisiana; and (3) permit of the further development of existing claims within withdrawn areas which have upon them one or more producing oil wells. These areas are already equipped with pipe lines and facilities for developing and transporting oil, and many of the interested individuals and corporations have equipment in the way of casing and other supplies which could be immediately utilized in the drilling of additional wells.

The most immediate results would be obtained from the lands mentioned in the above items 2 and 3, namely, proved lands which have not been developed by oil wells and lands within withdrawals but which have within their limits one or more producing oil wells at the present time.

During the past few years I have made a number of reports and suggestions to the Public Land Committees of Congress with respect to legislation of the character involved, and bills have passed one of the bodies of Congress, but none has received concurrent approval. I do not feel that I should at this time specifically indorse any particular measure, and consequently this report is designed to explain briefly why I believe the enactment of legislation for the development of the oil resources of the public domain would materially aid in obtaining an increased fuel supply in the immediate future. It must be obvious to anyone familiar with the situation that the existing withdrawals and controversies prevent the bringing of the oil from underground and into use, and the conditions described in the report of the United States Fuel Administrator in his report to the Senate, dated Sept. 10, 1918, document 277, and in my report responding to Senate resolution 301, which gave in some detail the present situation with special reference to gasoline, emphasize the importance and desirability of the enactment of legislation which will, while properly preserving the public interest, stimulate and encourage the production of oil from our public lands.

I am of the opinion, therefore, that viewed from any angle the passage of a leasing bill is desirable, and conditions possibly will arise that will make it distinctly a war measure. Respectfully,

VAN H. MANNING, Director.

### Shipments to Denmark Allowed

WASHINGTON, Sept. 20—The War Trade Board has concluded an agreement with a special Danish mission, allowing for the following annual quantities of supplies (in metric tons) for shipments to Denmark. The following list contains only those commodities which are of interest to the automotive industries:

Kerosene, gasoline, lubricating oils, and greases, crude petroleum and dark refuges, including not over 7000 tons lubricating oils.....	80,000
Copper and manufactures of (including brass).....	3,500
Brass wire.....	34
Brass wire screens for paper making..	20
Brass screws.....	36
Iron and steel products, including shipbuilding material (shipbuilding material to be subject to special agreement).....	150,000
Electric lamps.....	70
Nickel and manufactures.....	14

## War Board Controls Pig Tin

Users and Dealers to Be Licensed and Inventories to Be Made

WASHINGTON, Sept. 20—Control of domestic pig tin under a license system has been assumed by the War Industries Board. All users and dealers in pig tin will be licensed and a complete inventory of stocks on hand and unfilled contracts will be made and, if necessary, supplies will be redistributed to equalize them, according to essential uses. Full details of the licensing plan will be announced later. More than 2000 questionnaires have been sent to individuals and plants asking for information as regards the stocks of pig tin on hand and the unfilled contracts.

This action by the War Industries Board was forecast when announcement was made by B. M. Baruch, chairman of the board, that an inter-Allied pig tin pool had been arranged in conferences held in London between the L. L. Summers Commission, representing the War Industries Board, and representatives of Great Britain and other Allied nations.

Under this pool, which is in the nature of a beneficent monopoly, the world's supply of pig tin is allocated and distribution is made among the Allied countries according to the supply and their needs. The United States will get about 80,000 tons of pig tin, or approximately two-thirds of the world production.

The War Industries Board will supervise the allowance to this country. All imports of pig tin, tin ores and concentrates will be consigned to the American Iron and Steel Institute, and will be distributed to the licensees through the United States Steel Products Company. Prices will be regulated by the War Industries Board, and will be uniform and at a level that will encourage production in the tin mining countries, which are chiefly Great Britain and the Straits Settlements.

Aluminum and manufactures.....	132
Lead and manufactures.....	3,000
Tin and tin plate. Quantity to be later agreed	
Zinc sheets.....	390
Zinc and manufactures.....	2,700
Silver and manufactures.....	14
In addition various instruments for technical, scientific and nautical purposes (if approved), motors, automobiles and parts (excluding tires), electrical machinery, bicycles and bicycle parts (excluding tires), typewriters, accounting machines, office equipment, supplies, sundry machinery and parts (if approved) hand tools of various kinds, hardware, in quantities in accordance with actual Danish requirements for home consumption.	
Crude rubber.....	130
Bicycles tires.....	100
Motor and motorcycle covers and tubes..	250

### Patent Granted to Chevrolet Men

FLINT, MICH., Sept. 21—A patent has been granted Arthur C. Mason and T. Sturt, assignors to the Chevrolet Motor Co., on an automobile engine.

## War Board Controls Ocean Shipments

### Will Issue Both Import Licenses and Import License Numbers

WASHINGTON, Sept. 19—Changes in import ruling governing the certification of invoices for shipments by the American consular officers have been made by the War Trade Board. American consular officers will certify no invoices for ocean shipments to be made on or after Oct. 1, 1918, to the United States except on receipt of official notification from the War Trade Board of the issuance of an import license and import license number. After Oct. 1 consular officers are not permitted to accept import license numbers furnished by shippers as heretofore.

The number of any such import license, together with all necessary information, will, at the request and cost of the applicant for import license, be cabled or mailed by the War Trade Board to the Consular Officer whose consular district is designated by the applicant as the district from which the shipment to the United States will be made.

New forms of application for import licenses will soon be available, which will contain a blank to be filled out by the applicant for the purpose of indicating whether the applicant desires official notification of the issuance of the import license and of the number thereof to be sent by cablegram or by mail. The applicant designates in such blank the appropriate American Consular Officer. If the applicant is not able to supply the information at the time of the filing of his application, he should do so as soon thereafter as possible, either before or after the issuance of the license. All requests for such official notification made after the filing of the application should be, whether mailed or telegraphed, addressed as follows:

"Bureau of Imports,  
War Trade Board,  
Washington, D. C."

Such request should refer to the application or license number and should designate the appropriate Consular officer.

Import licenses will continue to be issued valid for a period of 90 days, but, under the new regulations, import licenses issued on or after October 1, 1918, will be valid if ocean shipments thereunder are made within 90 days from the date of such license. It will no longer be necessary, as in the case of licenses issued prior to October 1, 1918, that entry into the United States be made within the 90 days. This change will be of benefit to shippers and importers, who, heretofore, in many cases, have found it difficult to prepare merchandise for shipment, arrange for freight space, and obtain entry into the United States within 90 days.

With respect to import licenses which are outstanding and unused on October 1, 1918, if the shipments covered by such licenses have not been consigned by that date and the ocean shipments thereunder will be made on or after October 1, 1918, it will be necessary that official instructions be cabled to the appropriate Consulate officer at once by the War Trade Board. That there may be no delay in such shipments, the holders of such outstanding licenses should immediately notify the War Trade Board that they desire the appropriate American Consular officers to be officially notified by the War Trade Board, either by cablegram or letter, of the issuance of such outstanding licenses and of their numbers.

The date of ocean shipment, for purposes of these regulations, will be the date of a through ocean bill of lading to the United States.

Inasmuch as Consular officers will be governed, when consulting invoices, by the dates of the licenses and the dates of the through ocean bills of lading, importers are cautioned to keep accurate record of the expiration of dates of licenses in order that they make certain that the through ocean bills of lading are issued to them within the 90-day period, or, in the event that such through ocean bills of lading are not issued within such period, that they may apply in due time for extensions or new licenses, thus

avoiding delays and possible loss. Applications for extensions of expired licenses and for reissuances may be filed and will be disposed of according to the circumstances of each case.

It will be possible, as heretofore, to make partial shipments against a license, provided such shipments are made during the life of the license. All such partial shipments will be governed by the same rules as those that govern complete shipments.

Invoices for shipments of commodities covered by general import licenses known as "PBF" licenses will continue to be certified by Consular officers under the general license numbers, without official instructions governing each individual shipment (except that shipments covered by a general license "PBF" No. 1 require no certified invoices).

Following is a list including a number of the outstanding general or "PBF" import licenses:

PBF No. 12. Covering the importation of all commodities of the origin or destination specified below which arrive at any port of the United States or which are conveyed in transit through the territory of the United States either in bond or otherwise, as follows:

(a) Commodities originating in Canada or Newfoundland and destined for any country in the world; or originating in Great Britain, France or Italy or any of their European or West Indian possessions and destined for Canada or Newfoundland.

(b) Commodities originating in Great Britain, France or Italy and destined for any West Indian colony, possession or protectorate of said countries, or originating in any of said West Indian colonies, possessions or protectorates and destined for Great Britain, France or Italy, except (c) below.

(c) Commodities originating in Canada or Mexico and destined for another point in the same country, passing through the United States en route, except (e) below.

(d) Commodities of whatever origin or destination not now or hereafter placed on the restricted list, except (e) below.

(e) Shipments under paragraphs (b), (c) and (d) are not to be included in the general license when such shipment would cross the United States from an Atlantic to a Pacific or Gulf port, or from a Pacific to an Atlantic or Gulf port, or from a Gulf to an Atlantic or Pacific port.

PBF No. 14. Covering the importation of iron ore from Sweden and Spain when coming as ballast in vessels returning from these countries.

PBF No. 18. Covering the importation when shipped from Yarmouth, Nova Scotia, to Boston, Massachusetts, by vessel approved by the War Trade Board, of all commodities the importation of which is permitted without individual license overland or by the Great Lakes from Canada.

PBF No. 25. Covering the importation of all commodities arriving at United States ports in bond in transit to Canada, provided the Canadian import license covering the shipments or proper proof of the issuance of such license is presented to the Collector of Customs. (This supersedes PBF-12 as to in bond transit shipments to Canada.)

### Platinum Used Extensively for War Purposes

WASHINGTON, Sept. 19—Congressional discussion about the use of platinum yesterday developed that it is one of the very important commodities used in the war. The Signal Corps uses 500 ounces yearly for telephone, telegraph and radio work. The greatest use of platinum however, is in the manufacture of explosives, in the production of trinitrotoluol, gun cotton, dynamite and picric acid, which latter in turn is made with the use of nitric acid. Nitric acid is manufactured with the aid of sulphuric acid. Sulphuric acid is manufactured through two processes: Contact process and chamber process. Contact process is most frequently used and this requires platinum. A plant producing 20 tons of sulphuric acid in a day will require 350 or 400 ounces of platinum yearly. It is estimated that when our synthetic nitrate plants are completed they will need 20,000 ounces of platinum yearly.

## Use of Highways Advocated

### Fuel Administration Endorses Intensive Employment of Roads

WASHINGTON, Sept. 20—The United States Fuel Administration has endorsed the most extensive and efficient use possible of the highways in a letter to the Highways Transport Committee emphasizing the importance of the committee's program in connection with movement of coal from wagon mines. This letter from Cyrus Garnsey, Jr., Assistant Fuel Administrator, stated:

"We are also convinced that transportation resources can be greatly increased and larger tonnage movement of coal from wagon mines direct to consumers effected by applying all possible vehicles, horses and the necessary labor in line with national policies promulgated by you, and operating over suitable highways constantly maintained in efficient condition.

"For this reason we ask that you convey to our field organization our very real interest in this part of their work and assure them we desire to support their organization to the limit in their efforts to effect greater tonnage movement of coal over the highways from wagon mines to consumer.

"We suggest also that whenever conditions of roads, local legislation, lack of suitable equipment, and so forth, tend to impede the most effective and efficient movements, you will promptly bring these matters to our attention.

"To expedite the handling of these questions the Fuel Administration has committed them to its Mine Track Committee, composed of Frank G. Jones, chairman; Robert L. Ireland and S. A. Taylor."

### McGraw Advances Some Prices

EAST PALESTINE, OHIO, Sept. 22—The McGraw Tire & Rubber Co. has made a slight advance in the prices of certain sizes of its tires. There has been no change in the dealers' discounts.

### Commodities on Export Conservation List

WASHINGTON, Sept. 21—The following commodities have been placed on the export conservation list and will hereafter require special licenses for exportation:

Metallic aluminum and all articles containing 10 per cent or more (in weight) of metallic aluminum (individual licenses not required to Canada and Newfoundland), bichloride of tin, lead, lead pipe, lead sheet, oxide of tin, radium ores, radium salts, radium luminous compounds, tin salts, sundry articles either made of tin plate or coated or dipped in tin, titanium alloys, titanium compounds, titanium ores, uranium alloys, uranium ores, uranium salts.

Graham W. Brogan has been appointed advertising manager of the Duesenberg Motors Corp., Elizabeth, N. J. He was formerly assistant to the general sales manager.

A. C. McKibbin has retired as secretary of the Missouri State Highway Board. He retains his position as a member of the State Highway Board.

Frank H. Ball, formerly engineer of the Penberthy Injector Co., Detroit, has been made manager of the carburetor department of that company.

C. L. Fox, for 3½ yr. assistant sales manager of the Saxon Motor Car Corp., Detroit, has received an appointment to the officers' training camp at Jacksonville, Fla. He will report for duty about Oct. 1.

H. S. Ketchum, formerly New England district sales manager for the Cleveland Tractor Co., has been appointed by the McCord Mfg. Co., Detroit, as district sales manager for the Heath-Duplex folding delivery body. He will cover territory extending from Texas in the southwest to Florida in the southeast, and North Carolina in the northeast to Oklahoma in the northwest.

Frank C. Kip, sales manager of the Motor List Co., Detroit, and at one time sales promotion manager of the Packard Motor Car Co., has entered into Government work. Mr. Kip has been appointed to the Industrial Service Division of the Bureau of Labor Statistics, Department of Labor.

Ralph J. Handy, former distributor of the Tonford truck attachments in Detroit, has been appointed sales manager of the Lutton Truck Co., Youngstown, Ohio.

J. L. Hibbard, for 5 yr. associated with the Studebaker Corp. in its sales department, in charge of foreign sales, has been appointed foreign sales manager of the Cleveland Tractor Co.

W. H. Miller, for a number of years assistant manager of the South Bend Studebaker Corporation, has resigned to accept the position of district representative for the Garford Motor Truck Co., with headquarters at Kansas City.

H. S. Ketcham has resigned as New England district sales manager for the Cleveland Tractor Company and becomes southeastern and southwestern district sales manager for the Heath Duplex division of the McCord Manufacturing Company, Inc., Detroit.

John E. Garland, who has been in charge of motor car production of the Harroun Motors Corp., Wayne, Mich., has resigned to become assistant superintendent of production in the Ordnance Division. His former position has been filled by the promotion of E. Menke, formerly general foreman of automobile assembly.

## Men of the Industry

### *Changes in Personnel and Position*

#### Ellis on War Board

DETROIT, Sept. 23—Guy W. Ellis, formerly sales manager of the Maxwell-Chalmers factory branch, has been appointed secretary of the Wayne County War Board. He is also captain of the 550th machine gun company of the Michigan State troops.

Bruce A. Ott has been appointed general factory manager in charge of all plants of the Maxwell Motor Co. at Dayton, Ohio. Joseph H. Cooper remains as factory superintendent of Plant No. 1; I. B. Swegles as superintendent of Plant No. 2; J. C. Peil as superintendent of Plant No. 3, and Perry Kreitzer as factory superintendent of plant No. 4.

S. W. Monroe has been appointed manager of the Detroit branch of the Harroun Motors Corp. He has served the Harroun organization as middle western sales representative since the inception of the company, prior to which he was a district executive for the Maxwell Motor Co.

J. H. Gould, formerly of the J. H. Gould Co., Detroit, has been appointed chief engineer of the Buffalo Pressed Steel Co.

Leander J. Hoover, president of the Hoover Steel Ball Co., Ann Arbor, Mich., is dead after an illness of a month. Among the concerns he organized and of which he was president are the King Trailer Co., the Evertight Nut Co., Detroit, and the Fords Products Corp. He also organized the Parker Mfg. Co., manufacturer of chucks and arbors, and was its vice-president. He was also interested in a large number of other smaller concerns.

George A. Robson, formerly assistant advertising manager of the Chalmers Motor Co., Detroit, is now connected with the service staff of the Detroit *Saturday Night Press*.

J. E. Grady, sales manager of the Studebaker Corp. of Canada, Ltd., and manager of the Detroit branch, has resigned to become associated with R. T. Hodgkins, vice-president and general manager of the Cleveland Tractor Co., Cleveland.

J. L. Hibbard has been appointed foreign sales manager for the Cleveland Tractor Co., Cleveland. For the past five years he has been in charge of foreign sales for the Studebaker Corp.

Charles G. Percival, Captain, Ordnance Department, and Post Ordnance Officer, is editor of "The Bomb," which is published at American Military Camp 704, A. E. F.

#### Phelps Joins Duesenberg

WAUKESHA, WIS., Sept. 23—Fredrick Phelps, Waukesha, Wis., has accepted the position of director of the procurement division of the Duesenberg Motors Co., Elizabeth, N. J., and assumed his new duties Sept. 15. Phelps is head of the Arcadian Spring Co., Waukesha, one of the largest mineral water concerns in the world, which has closed its plant temporarily because of conditions arising out of the war.

#### Harroun Directorate Re-elected

WAYNE, MICH., Sept. 23—At the annual meeting of the Harroun Motors Corp., held in Wilmington, Del., the entire directorate was re-elected, including the following: President, John Guy Monihan; vice-president, Ray Harroun; secretary-treasurer, Howard F. Lea; John J. Plath, R. Ward Macey, A. L. Harroun, L. E. Moses, F. W. Vollbrecht, George G. Worthley, L. H. Rogers and Paul Hale Bruske.

#### Motor Transport Corps Wants Men

WASHINGTON, Sept. 23—The Motor Transport Corps needs the services of at least 200 men qualified to act as instructors in its training schools. Men of mature age who are either lawyers or teachers are requested to apply. Applicants will be given intensive training for 2 months with opportunities to secure commissions. Men versed in mechanical lines are preferred, but this knowledge is not necessary.

The Corps will open 10 new schools in various army camps shortly which will require 5000 officers, 30,000 non-commissioned officers and 100,000 men, and in these schools the enlisted men will secure intensive special training to fit them for the motor transport work.

Men who feel they can meet the qualifications and who desire to join the Corps, should communicate with the Chief of the Motor Transport Corps, 7th and B streets, Washington, D. C. Minor physical defects will be overlooked in men qualified mentally.

#### Expect Rise in Canadian Prices

VANCOUVER, B. C., Sept. 20—An increase of at least 10 per cent in the price of automobiles can be looked for in a very short time, according to the heads of several local automobile concerns. More than one head office has notified its branches to this effect, and it is expected that the increase will affect all the popular makes of cars. Shortage of cars, consequent upon the restriction of the government on raw materials, the scarcity of labor and the bending of the efforts of many companies toward the filling of war contracts are given as the chief reasons for the increase.

**Kuenz Radiator Co. Incorporated**

DETROIT, Sept. 23—The Kuenz Radiator Co. has been incorporated with a capital stock of \$100,000, the manufacturing plant being located in Toledo. The incorporators and officers are: President, J. H. Armstrong, of Cutting, Armstrong & Smith, Detroit, manufacturers of automobile parts; vice-president, J. A. Kuenz; secretary, S. C. Cobin; assistant secretary and general manager, E. C. Shields; treasurer, Charles D. Cutting, also of Cutting, Armstrong & Smith. The company has received a contract for 1500 radiators for De Haviland airplanes, the cost of which approximates \$250,000. Work will begin on this order Oct. 1, and is to be completed in 2 months.

**Oakland Making Additions**

PONTIAC, Mich., Sept. 20—The Oakland Motor Car Co. is erecting two additions, one on each side of the main entrance of the plant. The enlargement is designed to supply more room for lockers for men and women, to provide more office space, and to make possible expansion of the hospital ward. There will also be a lunchroom added for the benefit of workers who carry their lunches. The new quarters will be ready for occupancy within the next 6 weeks, it is expected.

**Another Ford Plant Taken by Government**

DETROIT, Sept. 23—Arrangements have been completed for the taking over by the Government of the Cincinnati plant of the Ford Motor Co. The plant will be devoted exclusively to the production of war materials.

**To Make New Lens**

NEWARK, N. J., Sept. 21—Edward S. Schmidt and J. H. Knox, 238 Central Avenue, trading as the S. & K. Specialty Co., have purchased the manufacturing and selling rights for the International lens, which is an anti-glare device for headlamps. It consists of a galvanized iron wire mesh covered with a semi-transparent coating which is non-breakable, waterproof and fireproof. The lenses are fitted inside the ordinary plain glass and sell for 75 cents a pair in any size. The factory is located at Irvington, N. J.

**Kales Stamping Expanding**

DETROIT, Sept. 19—The Kales Stamping Co., manufacturer of pressed metal parts, is erecting a two-story addition to its factory building on Lafayette Boulevard. The new structure is 47 by 67 ft. and contains 6000 sq. ft. of floor space. It will be used for storage and handling of stock. The work is expected to be completed this month.

**Columbia to Make Trucks and Trailer Service Parts**

DETROIT, Sept. 21—Production of the initial order of 500 1-ton trucks given the Columbia Motors Co. recently by the

## Current News of Factories

*Notes of New Plants—Old  
Ones Enlarged*

government will begin early in October and twenty-five are expected to be completed within the month. The company has also received an order for making all the service parts for the trailers it recently built for the government and also for those produced by other companies.

**To Market New Drive**

INDIANAPOLIS, Sept. 21—The Positive Drive, Inc., is a company incorporated to market or manufacture an automobile power transmission device invented by William H. Harris, 1226 Central Avenue. The company is capitalized at \$60,000, with incorporators named as William T. Rasmussen, Charles R. Yoke and Fred Davis. Other stockholders named in the incorporation papers are Dr. David L. Kahn and Leo Traugott. The device is one for the direct transmission of power to the wheels of automobiles whereby all wheels run at the same time with differential effect at corners and turns. The company may offer the invention on a royalty basis or decide later to manufacture it in Indianapolis.

**Dividends Declared**

The Michigan Drop Forge Co., Detroit, has declared its regular monthly dividend on common stock, payable Oct. 1 to stockholders of record Sept. 15.

The Willys-Overland Co., Toledo, has declared its regular quarterly dividend of 1½ per cent on preferred stock, payable Oct. 1 to stockholders of record Sept. 20.

The Chandler Motor Car Co., Cleveland, has declared its regular quarterly dividend of \$3 a share, payable Oct. 1 to stockholders of record Sept. 20.

The Hydraulic Pressed Steel Co., Cleveland, has declared the quarterly dividend of 1½ per cent on preferred stock and 2 per cent on common, payable Sept. 30 to stockholders of record Sept. 20.

The Standard Parts Co., Cleveland, has declared the regular quarterly dividend of 1½ per cent on preferred stock, payable Oct. 1. Books close Sept. 20.

The Cleveland Automatic Machine Co., Cleveland, has declared a 1½ per cent dividend on preferred stock, payable Oct. 1 to stockholders of record Sept. 20.

The Portage Rubber Co., Barberton, Ohio, has declared a quarterly dividend of 1½ per cent, payable Oct. 1 to stockholders of record Sept. 20.

The Goodyear Tire & Rubber Co., Akron, has declared the regular quarterly dividend of 1½ per cent on preferred stock, payable Oct. 1 to holders of record Sept. 20.

**Clutches Coming from Racine**

RACINE, WIS., Sept. 23—The Twin Disc Clutch Co. has been organized with an authorized capital stock of \$100,000 and is establishing a factory in the former plant of the Racine Auto Tire Co., at Fourteenth and Clark Streets, for the manufacture of clutches and other transmission devices and parts for motor vehicles and tractors. The incorporators include W. T. Shaughnessy, A. Francis, G. F. Garbutt, Julian Olds, J. A. Dietrich and Arthur B. Due, of the law firm of Quarles, Spence & Quarles, Milwaukee. The names of the actual stockholders in the new corporation are not divulged, but it is stated that several men associated with the Modine Mfg. Co., Racine, will have the actual control and management of the business.

**To Make Airplane Parts**

MILWAUKEE, WIS., Sept. 23—The Lochman-Mayhew High Speed Propeller Co. has been organized at Milwaukee to engage in the manufacture of aircraft and hydroplane parts. Articles of incorporation have been filed and give the capital stock as \$1,000, which is to be increased later. The principals in the new organization are Emil R. Lochman, owner of the Lochman Machine Co., and William H. Mayhew, first vice-president of the Mayhew company, cabinet and furniture manufacturer.

**Indicator Company Reorganizes**

GRAND RAPIDS, MICH., Sept. 20—The Auto Indicator Co. has been reorganized with a capitalization of \$50,000. The factory and salesrooms occupy the entire building at 209-217 Ottawa Avenue, northwest, formerly known as the Kent State Garage. The corporation is now manufacturing the Four-In-One Auto Indicator Safety Signal, a safety device for the rear of passenger cars or trucks to warn following cars of the driver's intentions.

The directors of the new corporation are: President, W. W. Huelster; vice-president, I. C. Cilley; secretary and treasurer, Joseph Renihan; general manager, V. I. Cilley; James Ritzema and Dr. E. O. Cilley.

**Addition for Detroit Twist Drill**

DETROIT, Sept. 21—The Detroit Twist Drill Co. has built an addition to its plant particularly to accommodate the increasing number of women employees. The new structure is 33 x 70 ft. with 6100 sq. ft. floor surface. The first floor will be used for steel storage and receiving room; the second floor for women's locker and lunch rooms and first aid room, and the third floor for the metallurgical laboratory, drafting room and women's instruction room. The building is of reinforced concrete.

**Delion Tire Increases Capital**

TRENTON, N. J., Sept. 21—The Delion Tire & Rubber Co. has increased its capital from \$700,000 to \$1,000,000.

## Coal Storage Limits Arranged

### Fuel Administration Schedules Storage Regulations for Essential Industries

WASHINGTON, Sept. 20—The United States Fuel Administration has arranged a schedule of coal storage for those industries which have been named essential and placed on the War Industries Board preference list. The regulations allow certain numbers of days of storage dependent upon the locality of the industry. There is also a set of regulations for consumers not on the preference list, allowing them a specific number of days storage.

The list is divided into 4 groups—each group comprising the same industries as named in the 4-group arrangement of the War Industries Board preferential list. The manufacturer, as for example a tractor maker, in group 3, with his factory in lower Michigan, will, according to the list, be allowed 60 days coal storage. A tractor maker in Maine will be allowed 105 days storage.

There is no restriction on the stocks of screenings which may be accumulated by either preferential or non-preferential consumers in Ohio, or lower Michigan, and there is no restriction on the stocks of Indiana, Illinois or western coal which consumers may obtain.

Following is the list showing the number of days of coal storage allowed various essential and non-essential industries, this list conforming strictly with the War Industries Board statement of preferential industries:

#### GROUP 1.

Maine, 135 days.  
Massachusetts, Vermont, New Hampshire, Northern New York, 105 days.  
Connecticut, Rhode Island, Southwestern New York, 90 days.  
Southeastern New York and New Jersey, 60 days.  
Delaware, Eastern Pennsylvania, Maryland, District of Columbia, Virginia, Florida and Western Ohio, 45 days.  
Western Pennsylvania, West Virginia, Eastern Kentucky, Eastern Ohio, 35 days.  
Lower Michigan, 90 days.

#### CONSUMERS IN GROUP 2.

Maine, 120 days.  
Massachusetts, Vermont, New Hampshire, Northern New York, 90 days.  
Connecticut, Rhode Island, Southwestern New York, 75 days.  
Southeastern New York and New Jersey, 50 days.  
Delaware, Eastern Pennsylvania, Maryland, District of Columbia, Virginia, Florida, Western Ohio, 40 days.  
Western Pennsylvania, West Virginia, Eastern Kentucky and Eastern Ohio, 30 days.  
Lower Michigan, 75 days.

#### CONSUMERS IN GROUP 3.

Maine, 103 days.  
Massachusetts, Vermont, New Hampshire, Northern New York, 75 days.  
Connecticut, Rhode Island, Southwestern New York, 60 days.  
Southeastern New York and New Jersey, 40 days.  
Delaware, Eastern Pennsylvania, Maryland, District of Columbia, Virginia, Florida, Western Ohio, 35 days.  
Western Pennsylvania, West Virginia, Eastern Kentucky and Eastern Ohio, 25 days.  
Lower Michigan, 60 days.

#### CONSUMERS IN GROUP 4.

Maine, 90 days.  
Massachusetts, Vermont, New Hampshire and Northern New York, 60 days.

Connecticut, Rhode Island and Southwestern New York, 45 days.  
Southeastern New York and New Jersey, 30 days.  
Delaware, Eastern Pennsylvania, Maryland, District of Columbia, Virginia, Florida and Western Ohio, 30 days.  
Western Pennsylvania, West Virginia, Eastern Kentucky and Eastern Ohio, 20 days.  
Lower Michigan, 45 days.

#### CONSUMERS NOT ON THE PREFERENCE LIST ARE LIMITED TO THE FOLLOWING STOCKS:

Maine, 45 days.  
Massachusetts, Vermont, New Hampshire and Northern New York, 30 days.  
Connecticut, Rhode Island, Southwestern New York, 20 days.  
Southeastern New York and New Jersey, 20 days.  
Delaware, Eastern Pennsylvania, Maryland, District of Columbia, Virginia, Florida and Western Ohio, 15 days.  
Western Pennsylvania, West Virginia, Eastern Kentucky and Eastern Ohio, 15 days.

#### 7579 Fordsons Sold by One Distributer in 22 Days

DEARBORN, MICH., Sept. 20—E. M. Vanderslice of Tulsa, Okla., distributor of Fordsons, has made a record in the distribution of tractors. He received his appointment as Fordson distributor July 3 and on July 25, only 22 days later, he had booked orders and signed contracts for 7579 tractors. This represents orders valued at \$5,500,000. Vanderslice recently visited the factory with a view of urging the company to immediately ship as many tractors as could be had for present distribution. A carload of 300 was started south last week. Because of the protracted drought throughout the south plowing for fall wheat had been impossible until now. This stimulated the demand for farming equipment and caused the Oklahoma State Council of Defense to send Henry Ford & Son a telegram urging the company to start a shipment to this territory as soon as possible. Another urgent call was received from Texas and a carload of 500 was dispatched.

#### Iron Ore Producers Granted Price Increase

WASHINGTON, Sept. 20—Iron ore producers were granted a slight increase in prices for the quarter beginning Oct. 1 by the price fixing committee of the War Industries Board last night after an all-day conference with representatives of the American Iron and Steel Institute. The extent of the increase was not announced. Decision as to new prices on pig iron was postponed until to-day.

The present price of iron ore is \$5.50 a ton, lower lake ports; pig iron \$32 a ton and foundry iron \$33. Steel prices average about 3¼ cents a pound.

#### 800,000 Tons of Steel Saved by Ford Action

DETROIT, Sept. 20—The suspension of passenger car manufacture at the Ford Motor Co. alone will effect a saving of 800,000 tons of high grade steel for the government. Had production at the plant continued to the limits allowed by the government for the remainder of the calendar year a total of 123,000 cars would have been produced during the last 6 months and each car would have required 1300 lb. of steel.

## Standard Contracts for War Work

### These Are Designed to Speed Up Production and Guard Against Fraud

WASHINGTON, Sept. 21—Standardized contracts will be used by the War Department hereafter, in so far as is possible, in making purchases. Clauses have been standardized and will be used in every form of contract. They are designed to speed up production, guard against fraud, protect labor interests and assure both the Government and the contractors against legal complications. All previous forms of contracts have been examined and used for compiling the new standardized ones.

To speed up settlements of disputes arising between the Government and the contractor regarding the adjustment of claims which might delay production during the settlement and further to make unnecessary the filing of lawsuits in the Court of Claims, a clause provides the means for the immediate adjustment of all such differences. In the event of the arising of any claims, doubts, or disputes as to the performance or non-performance of the contract which cannot be settled by mutual agreement, the question is placed before the Secretary of War or his duly authorized representative or representatives for adjustment. In the event that the matter is placed before a board, a majority decision of the latter shall be final but permission to appeal directly to the Secretary of War within a limited time is allowed.

The Government retains the right to terminate any contract in the public interest, and if it finds that the need for any contracted supplies no longer exists it can terminate the contract within a specified time. Definite provision is made for the payment of existing stocks and raw materials on hand for the completion of the contract and provision is made for the adjustment of all obligations assumed by the contractor for fulfilling this agreement. Arrangements are also made for the disposal of special facilities provided for the execution of the contract.

Three clauses are devoted to labor. One provides that in the cases specified by law the wages of laborers, operatives and mechanics doing any part of the work contemplated by the contract, in the employ of the contractor, shall be computed upon a basic day rate of eight hours' work, with overtime rates to be paid for not less than time and one-half time for all time in excess of eight hours.

In the event that labor disputes should arise directly affecting the performance of the contract or delaying its execution, the contractor may appeal to the Secretary of War for adjustment of the difficulty. The contractor is obligated to comply with such adjustment as may be made by the Secretary. If such a settlement involves an increase of wages, thereby placing a burden on the contractor, he will be compensated for the extra outlay. Likewise, in the event of a reduction of labor cost, the amount involved will be deducted from the cost in favor of the Government.

Contractors are obliged to comply with existing state laws and are also obligated not to employ in War Department contracts any minor under the age of 14 years or permit any minor between the ages of 14 and 16 years to work more than eight hours in any one day, more than six days in any one week, or before 6 a. m. or after 7 p. m. The employment of convict labor is prohibited, except in the event of an executive order and then only under the terms of such an order.

On cost-plus contracts provision is made for a rigid inspection of costs and the Government retains at all times the right to make checks and audits on materials and prices as well as setting up machinery of inspection to insure full value received. The accounting books of the contractor are always to be open to the Government's officers. The decision of the Accounting Officer in regard to proper costs shall prevail. The right to appeal directly to the Secretary of War is given to the contractor. The con-

tractor must comply with the ruling that in all cost-plus contracts proposed expenditures for labor and materials shall be approved in advance.

In this connection the War Department will follow its policy that wherever possible fixed price contracts shall be used, but where it is to the advantage of the Government to use a cost-plus contract, a cost-plus fixed compensation contract will be used. All such contracts are subject to review by the Superior Board of Contract Review of the General Staff. The covenant against contingent fees as prescribed by executive direction will be incorporated in the new contracts. In this the contractor expressly warrants that he has not employed a third person to solicit or obtain the contract in his behalf and that he has paid no fee to secure it.

Contractors are obliged to provide protection to their plants against espionage, fire, explosion, acts of war, and acts of enemy aliens. The contractor shall, when required, report to the Government the citizenship, country of birth or alien status of any or all of his employees. The Government retains the right to prevent the employment of suspected persons or to demand their discharge from the employment of the contractor.

If at any time the Government is able to provide materials to the contractor, the latter is obliged to accept them, if he has not already made commitments, arrangements being made for satisfactory compensation.

The various supply bureaus of the Army are now preparing to adopt the new contract form.

#### Washington-New York Air Mail Is 100 Per Cent Efficient

WASHINGTON, Sept. 21—The aerial mail service to Washington, Philadelphia and New York has scored 100 per cent daily thus far for September, despite the rainy weather period. The worst day was Sept. 18, when the airplanes left Washington and New York in the midst of storms. The machine leaving Washington had to be started in the hangar, and the landing gear of the plane sank into the mud up to the hubs before making the take-off from the ground. Notwithstanding this weather the trip from Washington to New York was made in 3 hr. and 5 min. The entire journey was made through rain and storm and landings in rain were effected in Philadelphia and New York.

Aviator Max Miller left New York on Sept. 19 for Clarion, Pa., to chart a more favorable route across the mountains in Pennsylvania than is found on the air line from Belmont to Cleveland. He will return from Clarion to-morrow.

#### U. S. Rubber to Issue Notes

NEW YORK, Sept. 22—The United States Rubber Co. probably will issue \$6,000,000 of 5-year 7 per cent notes. It is understood that the company has applied to the Capital Issues Committee for permission to make the issue. The new notes would be used in connection with the refunding of the \$9,000,000 General Rubber Co. debentures due Dec. 1.

#### On Export Conservation List

WASHINGTON, Sept. 23—The following commodities have been placed on the Export Conservation list, effective Sept. 24, 1918, and will hereafter require permits for exportation: Cadmium alloys, cadmium compounds, cotton airplane duck, ferrozirconium, zirconium alloys, zirconium compounds, zirconium metal, zirconium ores or concentrates.

## Better Bearings for Farm Equipment

### Experiments Being Made with Anti-Friction Bearings on Power Farm Equipment

CHICAGO, Sept. 20—Power farm operative equipment fitted with anti-friction bearings will be on the market next year if experiments now under way are completed in time. The new machinery will include both tillage and harvesting equipment. At various implement factories experiments are under way looking toward the early production of plows, cultivators, mowers, binders, threshing machines and other equipment, all with anti-friction bearings in place of the rough or babbitted bearings with which farm equipment of the past has been fitted.

Development in this direction has been made necessary by the demand for heavier and sturdier machines for use behind tractors. Experience has shown conclusively that farm operative equipment of the horse-drawn types will not stand up under tractor farming conditions. The greater speed of the tractor, and the greater concentration of power, together with the strains of continuous work, racked horse-drawn machinery to pieces and made the rapid depreciation on such machines a fact of great economic importance to the farmer.

Most pieces of farm operative equipment are kept for an entire year only to be used for a few days. When needed it is all important that they be in good working condition and that they be able to meet the demands which will be made upon them. With equipment of the old design there has been a loss of time amounting sometimes to as much as 25 per cent for oiling and otherwise preparing the machines for service. Also it developed that where machines, with the crude bearings which have been the rule, were used with tractors, frictional resistance increased tremendously and the machines soon became useless.

While the substitution of roller bearings for the old style bearings will increase the cost of the machines to the farmer to some extent, this will be far more than offset by the saving effected in time and in lengthening the life of the machines. An authority on this subject says that by the substitution of anti-friction bearings for the old style babbitted bearings in a threshing machine, for instance, there will be a saving of 10 hp. on the power required to operate it and a saving of at least four hours per day in oiling and attention. Of course, it is impossible at this time to say to what extent the life of machines will be extended, but it must be obvious that it will be considerable.

#### Mexican Oil Exports

TAMPICO, MEXICO, Sept. 21—Complete figures of the oil exportations through the ports of Tampico and Tuxpam for the month of August are now

available. The Penn-Mex Fuel Company's shipments did not come up to earlier estimates by about 200,000 barrels, but the total shipments of all the companies through the two ports exceeded the 5,000,000 barrel mark by 36,140 barrels. The exports were as follows:

Huasteca Petroleum Company, 1,563,759; Aguila (Eagle) Oil Company, 709,772; Penn-Mex Fuel Company, 448,724; Freeport Oil and Transportation Company, 448,771; Island Oil Company, 246,300; National Petroleum Company, 56,014; Mexican Gulf Petroleum Company, 258,099; the Texas Company, 177,868; East Coast Oil Company, 331,750; Cortez Oil Company, 309,500; Standard Oil Company, 485,584.

#### The Pfalz Single-Seater Fighter

(Continued from page 550)

flanges is by gluing only, no tacks or screws being employed. The spar is afterward covered for its entire length by fabric, to prevent moisture from attacking the internal glued joints and to reduce the risk of splitting. The fabric is not wrapped around the spar spirally but is laid on straight, finishing off along one corner of the spar. As in most machines, the spars are not placed with their vertical faces at right angles to the chord line but at right angles to the line of flight.

Reference has already been made to the struts connecting the body with the top plane, and to the fact that these struts are pivoted as shown in an accompanying illustration. A circular base plate is bolted to the body formers where these are crossed by the upper body rails. The base plate has welded to it a cup or socket into which fits a spherical male portion secured to a sheet steel shoe surrounding the lower end of the body struts. A taper pin passing through socket and ball secures the strut in place. The slot through the ball is of elliptical section to allow a certain amount of play for alignment.

Another sketch shows how the lower spars are attached to the wing roots formed integrally with the body. The fixed spar inside the body is rounded off at its outer end to a circular section. A steel cap surrounds the end of the spar root, to which it is secured, as far as we have been able to ascertain, by a single pin. This cap is surrounded by a collar incorporating a fork for the attachment of the lift cable, and terminates at its outer end in a steel piece shaped like an eyebolt. The inner end of the wing spar is also surrounded by a sleeve, this, however, being secured by two bolts, the inner of which is an eyebolt that serves as an anchorage for the internal drift wiring. The wing spar sleeve carries at its inner end the female portion of the joint, a forked end, which engages with the eyebolt of the fixed spar, the two being held together by a quick-release pin as shown. The ribs have been omitted in the larger drawing for the sake of clearness, but they are indicated in the smaller inset.

(To be concluded)

## Control of Moline to Overland

### Plow Company to Be Operated as Separate Concern—To Build Tractors in Toledo

TOLEDO, Sept. 25—The Willys-Overland Co. has obtained control of 51 per cent of the stock of the Moline Plow Co., Moline, Ill., which manufactures the Moline-Universal tractor and an extensive line of other farm implements. It is the plan of the Willys-Overland company to retain the Moline company practically intact except that Vice-President and General Manager Frank G. Allen will become president and general manager.

The Moline company will be operated as a separate organization, and according to John N. Willys no merger is contemplated, nor will there be any change in the financial status of the Moline company.

It is planned eventually to concentrate all manufacture of tractors at Toledo, and to this end the production of tractor engines will be commenced there at once. Steps are now being taken to transfer some of the machinery and manufacture of engines will be begun soon on a large scale. Within a year the entire tractor will be built in the Toledo shops, with the Moline and other shops to be devoted to the production of agricultural implements. The Moline company has eight plants, located in Moline, Chicago, Rock Island, Freeport, Poughkeepsie, Stoughton, Wis., and Minneapolis.

The Moline company was established in business in 1865 and incorporated as the Moline Plow Co. in 1870. In 1906 the Mandt Wagon Co., Stoughton, Wis., and the Henny Buggy Co., Freeport, Ill., were acquired. In 1909 the Monitor Drill Co., Minneapolis, was taken over, and in 1911 the Acme Steel Co., Chicago, and in 1912 the Adriance-Platt Co., Poughkeepsie. In the spring of 1916 the company commenced production of passenger cars, using one of the new factories at Freeport. In the fall of 1915 the business, good will and patents of the Universal Tractor Co. were acquired and a factory erected in Rock Island for their production.

The Moline company is capitalized at \$21,000,000 common, \$7,500,000 7 per cent cumulative first preferred and \$1,500,000 non-cumulative second preferred. Late in August an issue of \$6,000,000 serial notes was placed on the market.

At the time of the sale of these notes it was stated that the company's sales for the 11 months ending July 31, 1918, totalled \$17,315,036, as compared with \$13,140,450 for the preceding 12 months. At no time in its history has the Moline company been physically able to supply the demand for tractors. At the present time the production is running 54 a day and the company is 4800 machines in order.

It is likely that the selling forces of

the Overland and Moline companies will be combined. The Moline company has 22 branch houses and 30,000 dealers. The Overland company has more than 100 distributors and 8000 dealers.

The acquisition of the Moline company places the Overland company in a position where it is able to supply its representatives not only with passenger cars and motor trucks, but with tractors and also with airplanes. The latter includes the control of substantial interests in the Curtiss Aeroplane & Motor Corp., Buffalo, thus making the automotive field complete in so far as Overland is concerned.

### Truck Curtailment Protest (Continued from page 554)

war essentials, and that their production for such purposes must be facilitated; and further that in so far as motor trucks are employed in civilian industries for essential uses they constitute an important transportation medium, and any curtailment of such uses should be avoided as far as practicable."

As was shown in meetings previous to the issuance of this circular, more than 80 per cent of the truck consumers in this country are engaged in what can be called direct or indirect war work, or essential civilian industries. Consequently, the raising of this question of the essentialness of the motor truck by the War Industries Board at this time seems unreasonable to the truck makers. They declare that the essentialness of the truck has been proved and accepted by the War Industries Board.

### Glover Heads Motor Division (Continued from page 554)

The district offices organization includes the Chicago office, under Major M. B. Edgerton; Cleveland, under Captain D. S. Devore; New York, under Major E. L. Jacob, and Detroit, under Major G. D. Wilcox.

### Fair Success Follows Chicago Show

CHICAGO, Sept. 23—A fair degree of success from a standpoint of accessory business, a failure from a standpoint of general attendance and from truck and tractor business, is the only conclusion that can be reached regarding the Second Annual National Truck, Tractor and Accessory Exposition, which closed Saturday night after a run of a week at the Municipal Pier. A large proportion of the accessory exhibitors expressed themselves as being quite satisfied with the business results obtained. Many of them found a better business than they anticipated.

This seeming paradox of good business for many of the accessory dealers and a discouragingly small attendance comes about through the fact that the show was staged expressly for jobbers and dealers and set at a time when the jobbers and dealers are closing up their accessory lines for the coming season. Inasmuch as it appealed to the trade, the fact that there were not many people there who were solely sight-seers, from whom nothing could be expected more than a few retail orders, the lack of a crowd made it possible for those who came there direct for business to make their inspection of the different lines and conduct their negotiations without the jam of people with which we are accustomed to find the aisles crowded at the national shows.

## Tax Plan Unchanged by Congress

### Some Knots Regarding Tax on Used Cars Untangled—Each Buyer Must Pay Impost

WASHINGTON, Sept. 19—There has been no change in the proposed tax on passenger cars, trucks and gasoline in the new revenue bill, although there has been considerable discussion on the part of the House regarding the tax.

Some suggestions have been received by congressmen in favor of a yearly tax on the use of passenger cars based on their value instead of on the horsepower and suggesting the use of the used car lists used by the Chicago Automobile Trade Association as the basis of taxation. In discussion of the tax Congressman Treadway explained that the yearly tax will not apply to an automobile owned by an individual and left in the garage unused during the entire year, because the bill specifies that the tax will be collected on the use of automobiles.

Congressman Ellsworth stated that a number of dealers in used cars complained that under the horsepower tax plan a \$200 machine will pay the same tax as a \$5,000 one. Congressman Kitchin explained that while the machine is in the hands of the dealers for repairs, equipment or resale it is not subject to the tax, but as soon as it is purchased by an individual for his use and is used he will have to pay the license tax and not the sales tax. It was also explained that if automobiles changed hands four or five times in the course of the year each new user would have to pay the yearly license tax.

### New Directors for Standard Aircraft

ELIZABETH, N. J., Sept. 25—Joseph A. Bower, vice-president of the Liberty National Bank of New York, and Henry J. Fuller, vice-president of the Fairbanks-Morse Co., have been elected directors of the Standard Aircraft Corp. and the Standard Aero Corp. of New York.

The one truck exhibitor who sold a truck at the show said the sale was the result of a lead he had gotten outside and that the prospect came in at his telephoned request, although the opportunity of showing the truck at the Pier to the prospect permitted him to close the deal.

Foote Bros., exhibiting a planetary transmission for tractors, were the only people in the truck and tractor business that found the show worth while. They said the show gave them an opportunity to get some good factory prospects that they might not have gotten otherwise.

Opinions among the accessory exhibitors are divided. Those who exhibited with general publicity as one of the principal reasons were sadly disappointed, because the public was not on hand

## Bureau of Aircraft Purchases

WASHINGTON, Sept. 20—Following is a list of purchases contracted for by the Bureau of Aircraft Production:

Aug. 22, 1918

Dayton-Wright Airplane Corporation, Dayton, Ohio, spares for planes.  
Tennessee Valley Iron & Railroad Co., Collinswood, Tenn., wood.  
Frank P. Jones, 807 Liberty Building, Philadelphia, Pa., lumber.  
Standard Aircraft Corporation, Elizabeth, N. J., lumber.  
William Whitman & Co. (Inc.), 25 Madison Avenue, New York City, balloon cloth.  
The Lawton Mills Corporation, care of E. N. Morris, P. O. Box 1057, 86-88 Worth Street, New York City, balloon cloth.  
Wellington Sears & Co., 66 Worth Street, New York City, N. Y., balloon cloth.  
Wellington Sears & Co., 66 Worth Street, New York City, N. Y., balloon cloth.  
Coventry Co., Anthony, R. I., balloon cloth.  
West Woodworking Co., 308 North Ada Street, Chicago, Ill., propellers.  
Standard Aircraft Corporation, Elizabeth, N. J., airplane.  
Splitdorf Electrical Co., 98 Warren Street, Newark, N. J., magneto parts.

Aug. 24, 1918

Dayton Wright Airplane Co., Dayton, Ohio, spares for planes.  
Gray Tractor Co., (Inc.), Minneapolis, Minn., spare parts for tractors.  
F. S. Webster Co., 332-342 Congress Street, Boston, Mass., typewriter ribbon cloth.  
A. H. Wells & Co., Waterbury, Conn., copper tubing.  
Cyclemotor Corporation, Rochester, N. Y., engine spares.  
Howell & Lesser, San Francisco, Cal., airplanes.  
U. S. Aircraft Corporation, Red Wood City, Cal., airplanes.  
Livingston Radiator & Manufacturing Co., New York, N. Y., radiators.  
Union Switch & Signal Co., Swissvale, Pa., engines and spares.  
Curtiss Aeroplane & Motor Corporation, Buffalo, N. Y., reimbursement erecting and equipping building at Buffalo.

Aug. 26, 1918

Whittaker-Glessner Co., Portsmouth, Ohio, steel drums.  
Liberty Iron Works, Sacramento, Cal., airplanes.  
Curtiss Aeroplane & Motor Corporation, Buffalo, N. Y., spares for planes.  
American Propeller Co., Baltimore, Md., propellers.  
The Marlin-Rockwell Corporation, New York, N. Y., radiators for planes.  
Splitdorf Electrical Co., Newark, N. J., engine spares.  
Jones Metrola (Inc.), 29-31-33 West Thirty-fifth Street, New York City, N. Y., tachometers.  
Burke & James (Inc.), 240-258 East Ontario Street, Chicago, Ill., camera turret suspensions.

Aug. 27, 1918

Oxygen Gas Co., Kansas City, Mo., hydrogen gas.  
Wellington Sears & Co., 66 Worth Street, New York City, N. Y., finished balloon cloth.  
Wellington Sears & Co., 66 Worth Street, New York City, N. Y., balloon cloth.  
Wellington Sears & Co., 66 Worth Street, New York City, N. Y., balloon cloth.

## Contracts

Aug. 28, 1918

Wright-Martin Aircraft Corporation, New Brunswick, N. J., engine spares.  
Russell & Cowles, 99 Johns Street, New York, N. Y., motor boat.  
Field Mfg. Co., Owosso, Mich., crating machine shop truck bodies.  
Willard Storage Battery Co., Cleveland, Ohio, batteries.  
Electric Storage Battery Co., 1823-33 L Street, N.W., Washington, D. C., batteries.  
Sperry Gyroscope Co., Brooklyn, N. Y., air compasses.

Aug. 29, 1918

The Wood Mosaic Co., New Albany, Ind., lumber.  
Amos Lumber Co., Edinburg, Ind., lumber.  
Park Drop Forge Co., Cleveland, Ohio, crankshaft forgings.  
Livingston Radiator & Mfg. Co., Seventy-fifth Street and Amsterdam Avenue, New York, N. Y., radiators.  
Union Switch & Signal Co., Swissvale, Pa., engines.  
Standard Gauge Steel Co., Beaver Falls, Pa., connecting rods.

Aug. 30, 1918

Breese Veneer Co., Keneva, W. Va., lumber.  
John A. Roebbling's Sons Co., Trenton, N. J., balloon cable.  
American Steel & Wire Co., 30 Church Street, New York, N. Y., balloon cable.  
Union Switch & Signal Co., Swissvale, Pa., services and material in repairing engines.  
Niagara Motors Corporation, Dunkirk, N. Y., engine spares.  
Ford Motor Co., Detroit, Mich., cylinders.

Aug. 31, 1918

The Burd High Compression Ring Co., Rockford, Ill., engine spares.  
Trumpbour-Whitehead Brass & Copper Co. (Inc.), Canal, Mercer and Howard Streets, New York, N. Y., copper radiator tubes.  
Eastman Kodak Co., Rochester, N. Y., drum-developing machine.

Sept. 3, 1918

The Wright-Martin Aircraft Corporation, New Brunswick, N. J., camshafts.  
Wright-Martin Aircraft Corporation, New Brunswick, N. J., engine spares.  
Cincinnati Milling Machine Co., Cincinnati, Ohio, milling machine and attachment.  
The Steel-Alderfer Co., Cuyahoga Falls, Ohio, lumber.  
Burd High Compression Ring Co., Rockford, Ill., piston rings.  
Burd High Compression Ring Co., Rockford, Ill., piston rings.  
Burd High Compression Ring Co., Rockford, Ill., piston rings.  
The Hess-Bright Mfg. Co., Philadelphia, Pa., engine spares.

## Quartermaster Purchases

WASHINGTON, Sept. 20—Following is a list of contracts placed by the Quartermaster Department:

Aug. 24, 1918.

Chicago Flexible Shaft Co., Chicago, Ill., spare parts.  
Haverford Cycle Co., Philadelphia, Pa., bicycles.  
Kniffin & Demarest Co., New York City, lantern globes.  
Emerson - Brantingham Implement Co., Rockford, Ill., tractors.

## Navy Supply Bureau Contracts

WASHINGTON, Sept. 20—Following is a list of contracts placed by the Bureau of Supplies and Accounts of the Navy:

Aug. 23, 1918

Goodyear Tire & Rubber Co., Akron, Ohio, dynamite gas valves.

Aug. 24, 1918

Goodyear Tire & Rubber Co., Akron, Ohio, training students.

Aug. 30, 1918

J. B. Swomball Co. (Ltd.), Chatham, New Brunswick, aeroplane spruce.  
O'Brien (Ltd.), Nelson, New Brunswick, aeroplane spruce.  
Geo. Birchill & Sons, South Nelson, New Brunswick, aeroplane spruce.  
J. B. Ritchie Co., New Castle, New Brunswick, aeroplane spruce.  
Shires Lumber Co., Campbellton, New Brunswick, aeroplane spruce.  
Fraser Lumber Co., Edmeston, New Brunswick, aeroplane spruce.  
Richards Lumber Co., Campbellton, New Brunswick, aeroplane spruce.  
Wm. Rutherford & Son, Montreal, Quebec, aeroplane spruce.  
Geo. B. Goodfellow, Montreal, Quebec, aeroplane spruce.  
Colonial Lumber Co., Pembroke, Quebec, aeroplane spruce.  
P. Q. Lumber Co., care of Geo. B. Scott, 705 Sears Bldg. (Dalhousie, New Brunswick), Boston, Mass., aeroplane spruce.  
United States Light & Heat Corp., Niagara Falls, N. Y., batteries.

## Army Engineer Depot Places Contracts

WASHINGTON, Sept. 18—The following contracts were placed by the General Engineer Depot of the Army:

Aug. 23, 1918

International Harvester Corp., Chicago, Ill., tractors.  
Ford Motor Co., Detroit, Mich., parts for searchlight carriages.  
Adams & Westlake Co., Chicago, Ill., switch lamps.

## Hart-Parr Brake Tests

CHASE CITY, IOWA, Sept. 21—The Hart-Parr 30 tractor at the Salina National Demonstrations in the brake horsepower test on the prony brake carried a load of 31.13 brake horsepower for 30 min. The engine speed during this official trial averaged 731.8 r.p.m. This test was made with the thermometer at 109 deg. Fahr. in the shade.

## Calendar

## ENGINEERING

Nov. 14-15 New York. Society of Naval Architects and Marine Engineers. Twenty-sixth general meeting. Engineering Societies Bldg., 29 West 39th Street.

## ASSOCIATIONS

Oct. 7-12—Milwaukee. American Foundrymen's Assn. and 5 allied organizations. Milwaukee Auditorium.

## SHOWS

Sept. 23-28—Boise, Ida. Tractor demonstration (State Fair). J. C. Wooley, Moscow, Ida.

Oct. 1-5 — Washington, Ga. (Wilkes Co.). Tractor demonstrations, State Fair.

Oct. 12-19 — Atlanta. Tractor demonstrations Eastern State Fair and Automobile Exhibition.

Oct. 14-27—Dallas, Tex., Seventh Annual Texas Automobile Show. Texas State Fair.

Sept. 17-20 — Riverhead, L. I. Tractor demonstration (County Fair). Harry Lee, Secy.

Sept. 30-Oct. 4—Trenton, N. J. Tractor demonstration (Trenton Fair). Harry B. Salter, Supt.

Oct. 16-18—Ottawa, Ont., International Plowing Match. Tractor and Farm Machinery Demonstration. Experimental Farm.

Oct. 30-Nov. 4—Shreveport, La. Tractor demonstration. State Fair.

Nov. 11-16—Phoenix, Ariz. Tractor demonstration, State Fair.

## Hudson Dealers Are Ready for the Future

*"We have no other intention than to operate our service and parts station to give Hudson owners the best possible attention."*

Thus writes one Hudson dealer in response to the Hudson 100% war-work announcement. His answer is typical of practically all the rest.

They show a determination to "carry on," realizing that to preserve their identity and their connection with Hudson will be their greatest asset for the future after the war is won.

They know that the Super-Six has already undergone endurance tests which for severity cannot be

surpassed even if the war is prolonged far beyond present prospects.

Their confidence is complete that when peace comes again and more automobiles can be made, the 57,000 Super-Sixes now in service will have added irresistible evidence of super-quality to the prestige and good - will that Hudson has already earned.

In this certainty of Hudson Super-Six performance is their assurance of permanence and progress after the war.

HUDSON MOTOR CAR CO.

DETROIT, MICH.

## It Costs More to Be WITHOUT a UTILITY HEATER

Cold feet—cold all over—cold in the head—continuous, nagging discomfort—bad temper—lowered efficiency. These are a few things a cold passenger car or truck costs.

*Truck Manufacturers:* Utility Heaters are humane. Think of the man who drives the truck winter in and out. Make the Utility standard or at least optional equipment. Write us.

### A Model For Every Car

Utility Protected Heater for all enclosed 5 or 7 passenger cars. Price \$20.00.

Utility Front Seat Heater for roadsters, driving compartments of large cars and trucks. Price \$12.50.

Utility, Jr., Protected Heater for Fords and other small cars. Price \$9.00.

Utility De Luxe Protected Heater for 8-cylinder cars. Price \$25.00.

Handled by good dealers everywhere.  
Dealers: Stock from your jobber. Get your share of heater business this next six months.

## Aircraft Board Purposely Created Without Power

Its Sole Function Was Advisory, Not Executive—Its Great  
Mission Was to Make the Army and Navy  
Co-operate in Aviation

By David Beecroft

**N**EW YORK, Oct. 1—In the interim between the aircraft report of the subcommittee of the Senate Military Affairs Committee and the Hughes report, which is expected in a few weeks, it might be well to clear up a few misconceptions generally held regarding the aircraft organization as it existed up until this spring when Howard E. Coffin resigned and John F. Ryan was appointed to take his place.

The Aircraft Board from its inception was entirely an advisory organization rather than an executive one. It never possessed any executive power such as needed in placing a contract for Liberty engines or deHaviland 4 planes, but exercised only advisory power relating to such, the executive power for placing of orders or making decisions resting with the Army or Navy.

### Clearing House for Army and Navy

In the act creating the Aircraft Board, Oct. 1, 1917, it was very specifically stated that the board was to be purely advisory. It was always a clearing house for the Army and Navy. The inception of the board was to get the Army and Navy to play ball together if the phrase may be used, and the board has proven successful in this regard.

The Army and Navy were both apparently very zealous of their power and authority and this power

and authority were carefully protected in the act of Oct. 1, 1917, creating the Aircraft Board, for it specifies "that the board is hereby empowered under the direction and control of, and as authorized by, the Secretary of War and the Secretary of the Navy respectively, on behalf of the Department of War and Navy, to supervise and direct, in accordance with the requirements prescribed or approved by the respective departments, the purchase, production and manufacture of aircraft engines, etc. Provided, that the board *may* make recommendations as to contracts and their distribution in connection with the foregoing, *but every contract shall be made by the already constituted authorities and the respective departments.*"

### Limits Prescribed by the Board

This clearly shows the limits prescribed for the Aircraft Board. It is very specific that all contracts must be made by the Army and Navy which are the "already constituted authorities of the respective departments."

The act of Oct. 1, 1917, went further and very specifically placed not only limits on the power of the Aircraft Board but saw to it that the Aircraft Board would not have any opportunity to build up an organization that would in any wise take power from the army and navy. The act stated that there

## Text of the Act Creating An Aircraft Board

(Public—No. 48—65th Congress.)

(S. 2705.)

An Act to create the Aircraft Board and provide for its maintenance.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That for the purpose of expanding and co-ordinating the industrial activities relating to aircraft, or parts of aircraft, produced for any purpose in the United States, and to facilitate generally the development of air service, a board is hereby created to be known as the Aircraft Board, hereinafter referred to as the board.

Sec. 2. That the board shall number not more than nine in all, and shall include a civilian chairman, the Chief Signal Officer of the Army, and two other officers of the Army, to be appointed by the Secretary of War; the Chief Constructor of the Navy and two other officers of the Navy, to be appointed by the Secretary of the Navy; and two additional civilian members. The chairman and civilian members shall be appointed by the President, by and with the advice and consent of the Senate.

Sec. 3. That said board and tenure of office of the members thereof shall continue during the pleasure of the President, but not longer than six months after the present war. The civilian members of the board shall serve without compensation.

Sec. 4. That the board is hereby empowered, under the direction and control of and as authorized by the Secretary of War and the Secretary of the Navy respectively, on behalf of the Departments of War and Navy, to supervise and direct, **IN ACCORDANCE WITH THE REQUIREMENTS PRESCRIBED OR APPROVED BY THE RESPECTIVE DEPARTMENTS**, the purchase, production and manufacture of aircraft, engines, and all ordnance and instruments used in connection therewith, and accessories and materials therefor, including the purchase, lease, acquisition or construction of plants for the manufacture of air-

craft, engines and accessories: **Provided**, That the board may make recommendations as to contracts and their distribution in connection with the foregoing, but every contract shall be made by the already constituted authorities of the respective departments.

Sec. 5. That the board is also empowered to employ, either in the District of Columbia or elsewhere, such clerks and other employees as may be necessary to the conduct of its business, including such technical experts and advisers as may be found necessary, and to fix their salaries. Such salaries shall conform to those usually paid by the Government for similar service: **Provided**, That by unanimous approval of the board higher compensation may be paid to technical experts and advisers. The board may rent suitable offices in the District of Columbia or elsewhere, purchase necessary office equipment and supplies, including scientific publications and printing, and may incur necessary administrative and contingent expenses, and for all of the expenses enumerated in this paragraph there shall be allotted by the Chief Signal Officer of the Army for the fiscal year nineteen hundred and seventeen and nineteen hundred and eighteen the sum of \$100,000, or so much thereof as may be necessary, from any appropriation now existing for or hereinafter made to the Signal Corps of the Army, and such appropriation is hereby made available for these purposes: **Provided further**, That except upon the joint and concurrent approval of the Secretary of War and the Secretary of the Navy there shall not be established or maintained under the board any office or organization duplicating or replacing, in whole or in part, any office or organization now existing that can be properly established or maintained by appropriations made for or available for the military or naval services. **Provided further**, That a report shall be made to Congress on the first day of each regular session of the salaries paid from this appropriation to clerks and employees by grades, and the number in each such grade.

Approved, Oct. 1, 1917.

should be no organization of the Aircraft Board that would duplicate a single existing organization of either the Army or the Navy.

Here is how the act expressed it: "Provided further: that except upon the joint and concurrent approval of the Secretary of War and the Secretary of the Navy, there shall not be established or maintained under the board any office or organization duplicating or replacing, in whole or in part, any office or organization now existing that can be properly established or maintained by appropriations made for or available for the military or naval services."

This expressly forbade the board either to establish or maintain any office that would duplicate a single activity of either the Army or Navy.

But the act of Oct. 1, 1917, put a further restriction on the Aircraft Board and made it very certain that its powers would never be more than advisory.

It appropriated only \$100,000 for the Aircraft Board so that the Board had no funds to buy airplanes, develop airplane engines, engage aircraft engineers, erect testing laboratories or build experimental stations for aircraft development. There was only \$100,000 for the board.

Note the act of Oct. 1, 1917, on this financial aspect:

"The board is empowered to employ, either in the District of Columbia or elsewhere, such clerks and other employees as may be necessary to conduct the business, including such technical experts and advisers as may be found necessary, and to fix their salaries. Such salaries shall conform to those usually paid by the Government for similar service. **Provided**, that by unanimous approval of the Board higher compensation may be paid to technical experts and advisers. The board may rent suitable offices, purchase necessary office equipment and sup-

plies, including scientific publications and printing, and may incur necessary administrative and contingent expenses, and for all of the expenses enumerated there shall be . . . allotted \$100,000 for the fiscal year of 1918."

This clause of the act put the final possibility of any large or elaborate Aircraft Board organization entirely out of being. It was never intended that there should be such and there never has been such. The Aircraft Board was to be purely advisory and it has always remained so.

#### What Was Its Mission?

If the Aircraft Board was not to have any executive power, why was it created? What was its special mission? What was it designed for? As already stated, its leading mission was to get the Army and Navy to play ball together on matters relating to aviation. Here is how this was accomplished:

All technical decisions regarding aircraft matters in 1917 and 1918 were made by the joint Army and Navy technical committee composed of three representatives from the Army and three from the Navy. These six representatives were all regular Army and Navy men and no civilians were included.

Making technical decisions was the work of this joint technical committee, and no type of airplane was ever brought into production that was not approved by this joint technical committee. The programs for engines, planes and other activities were brought before the Aircraft Board by representatives of the Army and Navy after having been approved by the joint committee of the Army and Navy. When these programs were laid before the board it gave or withheld its approval as it saw fit.

The Aircraft Board had to deal entirely with this joint committee on all matters relating to aircraft design, engines, selection of types, etc. There seemed no possibility of getting the aviation departments of the Army and Navy to work together except through some civilian organization as the Aircraft Board. Such a situation was not confined to America.

#### England, Too, Had Trouble

From the beginning of the war England had troubles between her army and navy on matters relating to aviation. In England the formation of the Air Service, putting all aircraft activities under one head, brought this to an end. In America the

civilian Aircraft Board accomplished the desired end. The Army and Navy really played ball so far as aviation was concerned. The Aircraft Board was a success.

The Aircraft Board, although created by act, Oct. 1, 1917, was never given half an opportunity to show what it could do. Its three civilian members were not all appointed until late in February, so that although the board accomplished its mission it did so under a severe handicap.

Howard E. Coffin was not appointed chairman for some time and the two other civilian members were not appointed for months; in fact, it was February before the final appointment was made. Undoubtedly politics was largely responsible for the delay as numerous good names were offered but none of them was accepted. In the meantime, other names were brought up and one or another dropped without the Aircraft Board being even consulted.

Previous to the creation of the Aircraft Board on Oct. 1, 1917, the Aircraft Production Board had existed as a committee of the Council of National Defense, and as such possessed only advisory powers. The board was then largely civilian in its make-up and consisted of \$1 per year men. During this time Coffin was assisted by E. A. Deeds, S. D. Waldon and R. L. Montgomery.

It was in August, 1917, or near that time, when Deeds, Waldon and the others, except Coffin, went into the Signal Corps and as representatives of such had executive power which they did not have as members of the Aircraft Production Board. Some of these men filled dual capacities. At one hour of the day they were working as members of the Aircraft Production Board in a purely advisory capacity and the next hour may have been placing contracts and exercising other executive powers as a representative of the Signal Corps. They could not do such as a member of the board.

This may have been the reason why the Aircraft Production Board and later the Aircraft Board were blamed for a hundred things that they had no right to be blamed for. The acts were not committed by members of the Aircraft Board but by members of the Signal Corps.

In times of investigation and dispute we should give the devil his due and so the board must not be loaded with abuses over which it had no authority or control.

# Analysis of Automobile Merchandising in New Zealand

## PART I

### Advent of American Car in 1915 and 1916 Created' New Mode of Business—American Car Now Dominant— Service the Important Factor

### WOOL INDUSTRY AFFORDS GOOD TRUCK POSSIBILITIES —FOREIGN TRADE DEPARTMENT

By G. A. Worrall\*

**W**ELLINGTON, N. Z., Aug. 1—The war established the American motor car industry in New Zealand. It was the volumes of money that started to flow into the country in the latter half of 1915 and the first half of 1916 from the sale of wool for war purposes that started the stimulation that has continued almost up to to-day, at which time the American automobile is dominant in New Zealand. Approximately every nine out of ten automobiles met in the two islands are American cars.

In New Zealand as in America everything now dates from the war, that eventful August day in 1914. Events happened either before the war or since it started. The American car came after the war, and its entry was due to two factors: First, it was in 1914 and 1915 that production of the American car rose to unprecedented figures. The American production for 1914 was 573,114 automobiles. For 1915 it was 892,618; for 1916 it was 1,617,708, and for 1917 it was 1,938,778.

The second factor was the entry of European countries into the war. England dominated the New Zealand market in pre-war days. France had a slight foothold and Germany had a very small following. The American car was a very limited factor in New Zealand motoring previous to the war, Ford being the pioneer.

\*Mr. Worrall spent 11 months in New Zealand as special representative of the foreign department of the White Co. He traveled on both islands and studied conditions for automobiles and trucks.

To-day the American automobile is the only make being sold in New Zealand, in fact only American cars have sold since 1914, when the war automatically withdrew the European nations.

The coming of the American automobile to New Zealand in 1915 started what has become a veritable upheaval in the distribution and maintenance of automobiles. A new group of dealers has sprung up. This group is fashioned very largely after the American pattern of dealer. He is an exclusive dealer who sells one, two or perhaps three makes of American automobiles and also handles motor trucks, accessories and soon will be selling farm tractors and unit lighting outfits.

Simultaneously with the upgrowth of this new pattern of importer or distributor there has sprung up in New Zealand a complete new line of salesrooms for the trade. The modern automobile salesroom is seen in Wellington, Auckland, Christ Church, Dunedin and other cities

here, just as it is seen in Richmond, Va., in Ithaca, N. Y., or in Hutchinson, Kan. In some cities ten or eleven of these new salesrooms have been built since 1915. In smaller places five or six of such places have sprung up.

The development of the exclusive automobile and truck dealer housed in his new place of business brought with it a new chapter in service in New Zealand. Previous to the war, automobile service as you know it in America scarcely existed in New Zealand. - -

*Typical wool and dairy farmers of New Zealand. This group make up the board of directors of a dairy in Taranaki. They are in the truck market*

Very few if any of the dealers or importers carried an adequate supply of spare parts, so that very frequently automobiles were laid up for a month or two waiting for spares to arrive from England, France or Italy.

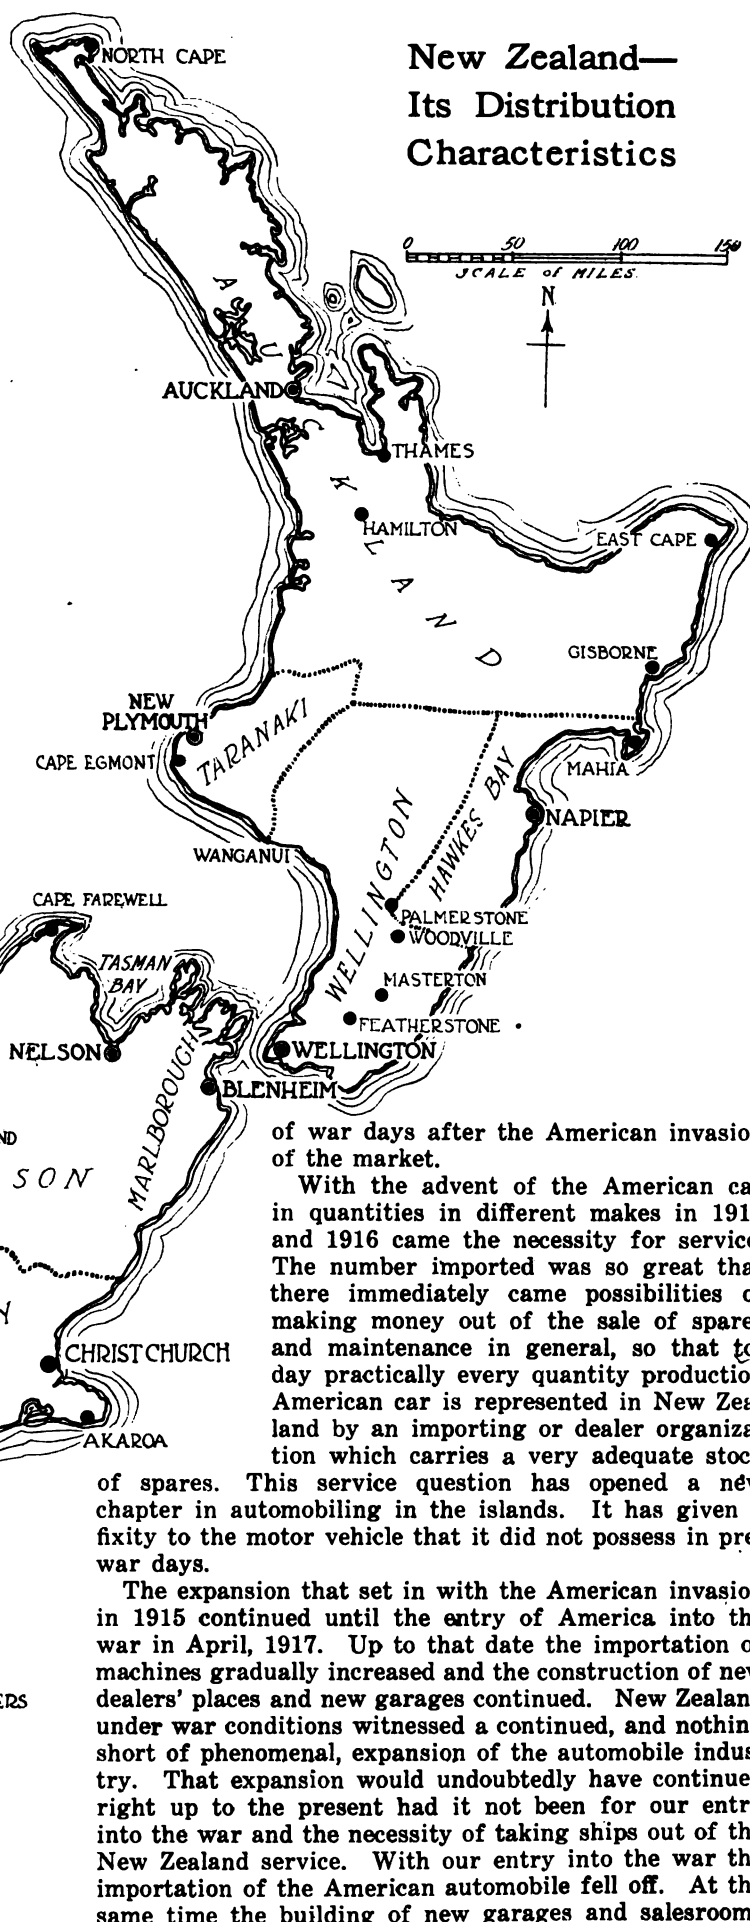

The New Zealand importer did not busy himself as he should have on this service problem, and it was equally remarkable that the European manufacturer did not insist on service as is being done today. The reason rested on two conditions:

One—The European maker had sold so few cars in the two islands that make up New Zealand that the necessity of adequate service had not existed.

Two—The automobile dealer was literally not a dealer but just an importer. He imported perhaps a hundred different lines of merchandise, and one of these was the automobile. He had no more right to be called an automobile importer than he had to be called a drug importer or a boot and shoe importer or an importer of merchandise of any character.

This importer got his 2.5 per cent commission on the automobile and passed it on to some agent who sold it. This importer or middle man was one of the worst enemies to the automobile industry in New Zealand. He did not take enough specific interest in the automobile to give it that attention which it merited. The importer got his commission out of the transaction and cared no more for the future welfare of the car than he cared for a stick of shaving soap. He failed to recognize that keeping the car in good running condition was a bigger factor than making the original sale. Naturally to such an importer the thought of service was almost foreign. He did not care to invest and tie up money in a stock of spares, and he was not sufficiently interested to demand that the dealers he sold to should stock up. As a matter of fact, the service end failed to exist and as a direct consequence the sale of cars in pre-war days was never on a scale with that

## New Zealand— Its Distribution Characteristics

of war days after the American invasion of the market.

With the advent of the American car in quantities in different makes in 1915 and 1916 came the necessity for service. The number imported was so great that there immediately came possibilities of making money out of the sale of spares and maintenance in general, so that today practically every quantity production American car is represented in New Zealand by an importing or dealer organization which carries a very adequate stock

of spares. This service question has opened a new chapter in automobiling in the islands. It has given a fixity to the motor vehicle that it did not possess in pre-war days.

The expansion that set in with the American invasion in 1915 continued until the entry of America into the war in April, 1917. Up to that date the importation of machines gradually increased and the construction of new dealers' places and new garages continued. New Zealand under war conditions witnessed a continued, and nothing short of phenomenal, expansion of the automobile industry. That expansion would undoubtedly have continued right up to the present had it not been for our entry into the war and the necessity of taking ships out of the New Zealand service. With our entry into the war the importation of the American automobile fell off. At the same time the building of new garages and salesrooms

## New Types of New Zealand Salesrooms Due To American Car Influence

*Salesroom of the Dominion Motor Vehicle Co. in Wellington. Chevrolet agents*

*Mangus-Sanderson, Ltd., handle Dodge cars and U. S. tires in this building in Wellington*

*The garage entrance of the Dominion Motor Vehicle Co. in Wellington*

*The Nattrass & Harris Motor Co., Ltd., entered the business in Wellington 2 years ago and now has a branch in Napier*

*The Colonial Motor Co., Ltd., is Ford agent for all New Zealand. The company assembles all cars here and will soon have a large assembling plant at Auckland*

*This is the establishment of the Buick sub-agent in Palmerstone on the North Island*

*A. Hatrick & Co., Ltd., of Wellington handle Overlands, Garford trucks and Hupmobiles*

## Typical New Zealand Roads and Truck Work in Wool Industry

*A 3-ton truck with a four long ton (2240 lb.) load 30 miles out of Wellington*

*Typical country carrier on a farm one mile off the main highway. This is a sheep station*

*A stretch of the 250-mile road from Wellington to Napier on the North Island. This part is between Wellington and Palmerstone*

*This Wellington carrier hauls all the coke from there to Petone, 20 miles away. He has 5 trucks and 40 horses*

*A specimen of Taranaki roads. There are 150 miles like this in the province running through dairy country*

*Typical Hawkes Bay road between Hawkes Bay and Palmerstone—a section between Napier and Wellington*

*Brooklyn Hill, overlooking Wellington. It is 1¼ miles long and has a gradient of 12 per cent. It is used as a truck and car demonstration hill by local dealers. It has a brick surface*

began falling off, until to-day it is practically at a standstill.

New Zealand is being particularly hard hit at present with the war. The two islands have a population of 1,100,000, and it has sent an army of 100,000 men to France. One out of every ten of the population has gone to France. At present New Zealand is drafting married men with two children. This shortage of men, which has been very acute during the last 2 years, has naturally cut into the demand for automobiles, a situation which is also certain to exhibit itself in America.

America might draw a parallel on the New Zealand man power question by attempting to visualize the American nation when it has over 10,000,000 men in France. When the American army reaches that figure American representation on the French field will bear the same relationship to the present army of New Zealand in France. The loss of man power in America will scarcely be so apparent when America has her army of 10,000,000 in France as in New Zealand to-day, because America as a country is better fitted with man-conserving machinery than New Zealand. New Zealand is essentially a pastoral country with wool, live stock and dairy products the main staples of the nation. Naturally such a nation, which is not in any sense a manufacturing nation, is not so well fitted mechanically to fit women into varied fields of industry as America with her leadership in mechanics and manufacture.

Although New Zealand is to-day to all appearances entirely within the grasp of the American automobile industry, due to the withdrawal of England from the market, many of the large distributors, or importers as they are preferably called here, have maintained strong affiliations with their British houses. One of the large importers recently admitted that he has orders for over 100 of a particular make of British car, and it is only natural to expect that just as soon as the war is over and British automobile makers get off their munition program and get back on automobiles, orders from many New Zealand dealers will start pouring in. The day war was declared New Zealand voted to send its army to support that of the British Empire, and ever since its energies have been centered on that goal. The 4 years of war have linked the New Zealander closer to the Britisher. It must be expected that these relationships will follow the signing of peace.

It is for this reason that the American manufacturer

*The road leading out of Wellington. It's a 14-mile climb on this road to the top of the hills beyond the city*

will have to look carefully to his New Zealand representation if he hopes to retain his hold on this market. It is expected that cheaper American prices will have a certain selling influence, but offsetting this will be the preferential import duties on British goods. At present the American pays 10 per cent more customs duty than the Britisher, and it will not be surprising if a still greater preference is given England and the other British colonies. In this connection Canada is bound to demonstrate its strength as a manufacturing country. The increase in manufacture in Canada due to munitions and war products in general has to a large extent established production manufacture there as was not known in pre-war days. This is bound to have an effect on after-war manufacture.

New Zealand, notwithstanding the war, will be a potential buying country, notwithstanding its small population, which is little more than Uruguay in South America, and only one-fifth of Australia or one-eighth of Canada. The two islands, with their 1,100,000 population, have practically all of this as a possible buying field. The entire population is white and almost exclusively descended from English, Irish, Scotch and Welsh stock. There are 45,000 natives known as Maoris—Mow-rees. These are the aborigines. They are intelligent but perhaps lazy. A percentage of them are

car buyers. They are all land settlers, and their property is protected by the government to such an extent that it cannot be sold and they cannot be dispossessed of it. In addition, the population includes 4000 Germans and perhaps 3000 Chinese.

With these people the five and seven-passenger touring cars are the dominating vehicles. You rarely see a limousine in any of the New Zealand cities. You never see a sedan. The runabout is not nearly so popular in proportion to numbers as in America. The New Zealander is a man of relatively large family and the family car is practically as popular as in Argentina or Brazil.

The greatest class of buyers is the farmer, which in New Zealand is a much broader term than in America. The largest farmers are sheep raisers, as sheep raising is the first industry in New Zealand. These sheep raisers are termed station owners, a term parallel to ranchman in America or estanciero in Argentina. Some of them have over 100,000 sheep, but the average small station owner will have 5000 sheep. Recently the government has taken a hand in the sheep raising work and is reducing the size of the sheep ranches, so that each year finds an increasing number of station owners.

These station owners invariably live on their stations or sheep farms. Some of them have their city homes,

*This 12-year-old boy of Taranaki regularly drives this 3-ton White over the one-mile stretch from and to the railroad depot*

but in general they may be from 50 to 75 miles from a city. These small station owners have always been the buyers of cars. You see many of these station owners with such English cars as Talbot, Rolls Royce, Daimler, Rover, Swift, Crossley and such other European makes as Minerva, Renault and Peugeot. Fiat and Lancia both have a good following. These small station owners have been and still are big buyers of American cars. They use their cars exclusively in the country, and 65 per cent of the car use is over metal or macadam roads and 35 per cent over dirt roads.

The second class of buyers is the city owner, which is made up of the same kind of buyer as an American city of 100,000 population. There are garages in every city of 1000 population up. There are salesrooms in every town of 5000 up, although there are quite a few smaller towns that have salesrooms. Gasoline is on sale in every village, although just at present the sale of it is being curtailed. Many dealers are only getting 50 per cent as much gasoline now as they got a year ago. The price has risen from \$5 for a case of 8 imperial gallons up to \$8 and \$10 for the same quantity. A price of \$1 per gallon has not been unusual during the past 4 months. The most of the gasoline comes from Sumatra and America. The Sumatra product is known as Shell spirit. It all comes in cases of two tins, each tin containing 4 imperial gallons. The imperial gallon is one-fifth larger than the American gallon.

The generally good roads of New Zealand have been a potent factor in the sale of automobiles to date. Only the main roads are metal or macadam. There is a linkage of metal roads connecting practically all cities of 5000 and up. Take an example: The City of Wellington, 73,000, is one of the two main cities in the northern island. From Wellington good roads radiate to Featherstone, 30 miles, and thence on 50 miles to Masterton and thence 50 miles further to Woodville. There is a good road radiating in another direction to Palmerston, 100 miles, and from here it continues 150 miles further into the interior. The road situation radiating out of Wellington is typical of that radiating out of such other cities as Christ Church and Dunedin in the South Island.

*(To be continued)*

*On this road out of Wellington it is a 1½-hour steady climb in a touring car. Wool comes down this 25-mile hill from the outlying country*

# The Army's Ambulance Program

**Automotive Equipment Comprises Ambulances on G. M. C. and Ford Chassis  
—Spare Parts Trailer—Collapsible Motorcycle—A Field Litter  
Which May Be Towed or Pulled by Men**

WASHINGTON, Sept. 27.—With the completion of the designs for the several standard machines necessary for the Medical Department Ambulance Service, the program has been definitely settled and production has started. In some instances, as with the standard ambulance, quantity production is under way. The ambulance program comprises:

1—The standard army ambulance, which is made up of the General Motors Co.  $\frac{3}{4}$ -ton truck No. 16 chassis combined with an especially designed body.

2—The U. S. Army service ambulance, which is a Ford chassis slightly redesigned together with an especially constructed body.

3—A spare parts trailmobile.

4—The Indian motorcycle, military type.

5—A specially constructed litter carrier trailer.

At the beginning of the war the only type of ambulance was a G. M. C. chassis equipped with an open stake

body. The new standardized ambulance, which is built on what is known as the AA chassis, which is the G. M. C. No. 16, is known in the service as type B 1918. The body panels are made of agasote. The dash is entirely of steel. It is so designed that it is shipped knocked down in four units on which the fixtures are already assembled. All of the holes in each unit are jig drilled, allowing for interchangeability of parts and for quick repairs.

The ambulance has a capacity for four wounded men prone and for eight sitting. The bodies are being manufactured by the Elkhart Carriage Co., Elkhart, Ind., and the Anderson Electric Co., Detroit, Mich. Doors are so arranged in the sides that medical attendance can be given to the wounded soldiers while they lie prone.

The Ford ambulance, which is known as the service ambulance, is radically different from the original type which has been supplied to the Allies and the Red Cross. The body is made of agasote and is sufficiently long to

*Two views of the new standard Ford ambulance provided the U. S. Army following designs by the Motor Ambulance Service section under Major Fishleigh. The body is made of agasote throughout, is long enough to accommodate the litters, and a redesign of the spring suspension allows an extra 15 in. of wheelbase*

*The original Ford ambulance which has been supplied in great numbers to the Allies and to the Red Cross. The canvas hoods sticking out in the rear were arranged to care for the ends of the litters. The bodies on these were made of paper, cardboard, wood, or cotton and the tops, of cloth held in place by wooden slats*

Above—The new model B 1918 standard U. S. Army ambulance. The body is made of agasote. The chassis is the G. M. C.  $\frac{3}{4}$ -ton model No. 16. The spare parts trailer can be seen attached to the truck. Below—The rear of the spare parts trailer with the doors open and the shelf let down, making a mobile repairshop

A rear view of the standard U. S. Army ambulance, loaded

A test of the U. S. Army standard ambulance, the B 1918, carrying 2300 lb., an overload of 800 lb.

*Above, the standard U. S. Army litter carrier trailer, attached to the towing ambulance and, below, the standard litter carrier trailer with the curtains up showing the wounded soldiers lying prone and the method of using manpower*

completely allow for the litters. In the original type the litters extended beyond the body. The Medical Department under the direction of Major W. T. Fishleigh redesigned the chassis to secure 15 inches more wheelbase and in that way eliminated the great amount of spring trouble which had previously been encountered. Gabriel snubbers are used. The steel dash has been changed to a larger size, affording more protection to the driver.

#### Can Accommodate Six Men

The capacity of the Ford is three men prone, two lying on the floor and one in a litter swung on straps, or four sitting. All in all, the new type of Ford service ambulance is an exact duplicate of the standard B 1918 ambulance except that it is smaller.

Spare parts for a complete company of 12 ambulances are carried in a trailer made by the Sechler Co. The trailer, which is towed by one of the ambulances, has a body made by the Glascock Co., Muncie, Ind., which, in addition to operating as a storehouse for parts, is so constructed that the rear can be opened and protected by a tarpaulin and converted into a work-

shop. The larger parts are carried in the forward body of the trailer, while the rear is divided into bins that are movable and arranged on shelves. Each bin is numbered. Each small part is tagged and numbered and an index card is fastened to the inside of the rear door, which shows the exact location of each part in the bin.

The Indian military model motorcycle, which forms a part of the standard equipment, is collapsible and consequently saves shipping space. This motorcycle differs from the 1917 type in that it carries a separate magneto instead of a magneto dynamo.

#### Litter Trailer Holds Two Men

The field litter carrier, which is constructed in the form of a trailer and is either towed by a truck or by the soldiers, is being manufactured by Mitchell Motor Car Co., Racine, Wis. The wheels are interchangeable with the wheels of the motorcycle side car. The litter trailer has a capacity for two men prone. It is so constructed that it can be shipped knocked down. One of its chief features is that it is possible to take it by handpower into the trenches to take up the wounded awaiting removal.

Spare parts are also carried in the towing ambulance, including chiefly the larger parts, the wheels, radiators, front axles, tires, etc. The motorcycles also carry small spare parts stocks under the seats. In fact, each ambulance, trailer and motorcycle is designed to be self-sustaining to a degree, while each company of 12 ambulances and the trailer is intended to be entirely self-sustaining and independent

of garages or base service stations which were necessary heretofore.

The companies are trained as self-sustaining units.

*The spare parts trailer in the crate as it is shipped abroad. The boxes beneath the trailer are hauled in the towing ambulance and contain the larger repair parts*

Right—The original type of U. S. Army ambulance, with the open stake body mounted on a G. M. C. chassis. Below—The U. S. Army Medical Department standard motorcycle, set up and also ready for shipment

## Utah Shale Beds Provide Large Oil Supply

**T**HAT there are vast resources of oil in shale beds throughout the United States is indicated by a report estimating that 42,800,000,000 barrels of crude shale oil and 500,000,000 tons of ammonium sulphate by-product are located in the Utah portion of the Uinta basin, lying in the northeast section of the State. The report of D. E. Winchester, issued by the U. S. Geological Survey of the Department of the Interior, indicates thickness and richness of oil shale beds in many places. Because of the demand for gasoline and for crude oil from which it is made, as well as for the ammonia by-product which is used in fertilizers, rapid progress is being made in producing these materials by investigation, experiments and general development. More than a dozen large companies have been organized in Colorado, Nevada, Montana, Utah and Wyoming and are now experimenting to determine the most efficient and economical way to produce oil from the shale. Aerial tramways are being built to bring the shale from mines opened high on the mountains to retorts built in the valleys near water and other lines of transportation.

### Dyes Being Produced from Shale

Experiments are also proving that numerous useful commodities can be made from the shales, such as dyes, explosives and substitutes for rubber, as well as gasoline, kerosene, paraffin and flotation oil, but the industry is not yet enough advanced to tell which of these products or how many can be manufactured at a profit. It is now considered likely that the by-products will prove most profitable.

The Utah oil shale is black or brownish black, finely grained, generally free from grit. It is tough and flexible. When ignited with a match the oil shale burns

with a sooty yellow flame. In order to obtain its content of oil the shale will have to be mined like coal, crushed and distilled in huge retorts, in which it gives off crude shale oil, ammonia, fuel gas and other possibly valuable products. Though some of the shale has on distillation yielded more than 2 barrels of oil to the ton, very little of the oil is in the shale in the form of oil. There is much partly bituminized vegetable matter in the shale which can be converted into oil by heat.

Freshly broken oil shale gives off a peculiar odor similar to that of crude petroleum.

Most oils obtained from the distillation of shale are reddish brown and at ordinary temperatures range from a thin liquid to a semi-solid vaseline-like product. The specific gravity of shale oil obtained in the field apparatus ranges from 32.98 degrees Baumé to 26.14 degrees Baumé. It is probable, says the report, that the large part of the difference in the oil from different shale is due to variations in the temperature of distillation. Fractionation of shale oil produces: gasoline (distillate to 150 degrees C.), 7 to 12 per cent; kerosene (150 degrees —300 degrees C.), 28.5 to 49 per cent; asphalt, 0.47 to 4.10 per cent; paraffin, 1.63 to 9.21 per cent; sulphur, 0.40 to 1.42 per cent; nitrogen, 0.887 to 2.198 per cent.

The large percentage of nitrogen it is believed will be lessened in commercial practice by injection of steam during distillation.

The refining of shale oil is a complicated process owing to the many distillations necessary to successfully separate the different ingredients which have varying degrees of volatility and specific gravity. Although the products of the American oil-shale industry will probably differ from the Scottish, where the profit is mainly derived from liquid and solid products, it is expected that the variety of American products will be large also.

# The Need for a New Incentive for the Industrial Worker

The Job Alone Does Not Supply It No Matter What It Pays or How Few the Hours It Takes—Maintaining Industrial Morale

By Harry Tipper

THE announcements of the Midvale Steel & Ordnance Company and the Lukens Steel Company regarding their adoption of co-operative administration deserve the thoughtful attention of the manufacturers of automotive apparatus. The steel companies are thoroughly organized and the business as a whole has an enviable reputation of farsightedness in its dealings with workers. Moreover, this is not the first experiment of the kind in the business, as the Colorado Fuel & Iron Company has had a somewhat similar one in process for about three years. The two significant statements in the announcement of the Midvale Steel & Ordnance Company are as follows:

"... recognizing the fact that the prosperity of their companies is inseparably bound up with the general welfare of their employees, propose, with the co-operation and assent of their employees and for their mutual interests, to establish a plan for representation of employees, which shall hereafter govern all relations between the companies and their employees."

"We recognize the right of wage-earners to bargain collectively with their employers and we hereby invite all employees to meet with the officers of their respective companies for the purpose of considering, and, if practicable, adopting a plan of representation by the employees, which shall be thoroughly democratic and entirely free from interference by the companies or any official or agent thereof."

## Guide-Posts for the Manufacturer

This war has indicated, to the student of labor questions and ideas, a number of guide-posts which should be of the greatest value to the manufacturer, whose most important problem is, and will be, the question of how to handle labor so as to procure the most stable and valuable condition. These guide-posts are to be found in the reports of the commissions who have studied labor under war-time conditions in Great Britain, in the history of the strikes over there, in the history of war-time strikes over here and the condition of labor, as shown by the turnover, the production efficiency during the war-time conditions.

The announcement of the Midvale Steel & Ordnance Company shows that the executives of this company have seen at least two of these guide-posts and are to that extent endeavoring to meet the situation in an enlightened and far-sighted way.

It will be noted that the first paragraph of the announcement states specifically that the company proposes, with the co-operation and assent of their employees, to establish a plan for representation of employees, which shall hereafter govern all relations between the companies and their employees.

The epochal character of this statement rests in the

recognition of the right, or at any rate the desirability, of the worker having a share in the responsibility for the conditions of his work and remuneration in the particular organization in which he is working.

This announcement recognizes the fact that neither high wages nor shorter hours are in themselves sufficient incentives to secure the maximum production nor the proper co-operative spirit.

It recognizes the fact that so long as the workmen can only secure representation (in their disputes with employers) through the use of general labor bodies, the organization incentive, upon which the manufacturer's welfare depends, is still wanting.

It suggests a recognition of the fact that none of the material things, wages, hours, good factory conditions, steady employment, can cut down the turnover, speed up the individual production, cut out the absences from the shop, or remove the suspicion which has characterized all the disputes between employer and employees under the present system. All these things have, from time to time, provided a temporary relief, but they have not removed the fundamental troubles, nor lessened the number of strikes, disputes, or difficulties with production.

## High Wages Do Not Provide a True Incentive

This war has provided the workers of all ranks with prosperity greater than any which they have enjoyed during the memory of any of the workers who are so benefited. It has enabled them to make their own terms as to pay, to secure steady employment and to avoid any of those uncertain conditions which usually interfere seriously with the earning capacity of the average worker.

Yet the record has been the same in Europe and here, the high wages have not kept the worker busy all the time, but have seriously cut into his hours of labor, unless the incentive of patriotism has done what the high wages could not do—waked his sense of responsibility. The reports of industries, where the high wages of the workers have resulted in a serious decrease in the number of days worked, if gathered together for the Allied countries for the period of the war, would show the general failure of prosperity to keep the worker to his work, or to stop the strikes, disputes and other indications of continuing discontent. It has been necessary to provide, in the appeal to patriotism, in the education upon the aims and necessities of the war, the incentive which had not been supplied by all the material progress which the worker has made.

## Patriotism the Present Stabilizer

In this country, since April, 1917, the records of disputes, strikes and other causes of loss of production, as well as the important cause of absence from work, have

been met successfully only when the patriotic appeal has shown the worker a real, definite and idealistic reason for doing his utmost and accepting some difficulties.

In fact, this has become so generally recognized that it is continually used to bring the mass of workers into the unity of action that alone will give the full power to the war machine.

Of course, the experiences of this war have indicated a great many other points in connection with the labor question which cannot be touched upon in this article, but must be left for future discussions. The points to be noted now are the necessity for some organization incentive to the worker in that organization and the fact that the job alone does not provide that incentive, no matter what it pays nor how comfortable its conditions are.

The writer was for several years engaged in factory work, and in the course of that training operated every machine in the factory for considerable periods of time, keeping up with the other operators and handling every bit of the routine of the matter. During the same time his spare moments were mostly spent in the company of skilled labor union men, getting their point of view, their ideas and their outlook. Very few of the operations which he had to undertake provided any incentive in themselves, once they were mastered. In fact, they became so irksome from their cramped requirement of mental and physical concentration that the one outstanding thought of importance was—how to get away from the monotony.

### Most Work Lacking in Incentive

From a careful examination of industrial work it is a conservative estimate to say that 75 per cent of the work in industry is repetitive, monotonous and lacking in any requirement which will supply either the incentive to good work or the incentive to keep working.

In war time we have successfully appealed to the instinctive ideal of citizenship to provide that incentive, but in peace times we have had no such ideal to appeal to and the material desire of the worker is paramount—the desire to escape from the monotony of his work and secure as much money as possible for the little work he is obliged to do.

This latter, the material desire, has found its expression in the labor union, and, among the more discontented spirits, in the political ideals of syndicalism and communistic collectivism, all of which attempt to cure the trouble by aggravating it.

The real necessity of the case is a co-operative spirit in the manufacturing organization, which can find its expression in some such plan as that adopted by the Colorado Fuel & Iron Company and those now announced by the other steel companies named.

It is not merely that such a step is morally desirable, but it is necessary for the economic stability and progress of industry as a financial matter. It is obvious to the student of human affairs that we are in danger of industrial turmoil, which may be more disastrous than the turmoil of the present war, unless steps are taken to supply some of the necessities for co-operative working out of these important industrial humanity problems.

### Industrial Morale

It is really a consideration of industrial "morale" and the means which are necessary to create a splendid morale and keep it.

We have discovered the tremendous importance of morale in soldiers, and how it can nullify advantages

in guns, transport, and all other equipment. We have seen the greatest war machine in the world stopped by men who were unprepared a few months previously, and we still marvel at the miracle of it. We have seen the Allies in four years outmaneuver all the science and diligent operations of a fifty-year preparation.

In thinking of this it is well to remember that this is an industrial war.

The whole of Great Britain has been made over industrially in order to fight—and this has been accomplished in less than one-tenth of the time the war was originally prepared. In a few months the United States has created new industries and brought them to such a pitch of perfection that they equal or surpass those which were slowly accumulated over many years of experience.

### The War's Lessons for the Manufacturer

As this is an industrial war, what can industry get from its lessons in the importance of morale, incentive, the ease with which technical advantage can be lost or overcome, and the splendor, character and possibilities of the individual when he is aroused?

They show on the positive side what a real incentive will accomplish, while our continual industrial difficulties show what a lack of incentive will disorganize.

We are providing millions of our workers with an incentive which has given them a glimpse of their own possibilities and importance. We have sent millions of them to work and fight for this incentive on the most dangerous mission that most of them have experienced—with the smallest pay they have ever received.

How are we to change industry so that it shall be up to the level of these men? How will we make it possible for them to reconcile their new sense of justice, democracy, their own power and individual capacity with the industrial organization to which a good many millions of them must return?

Obviously we must be prepared to give the human side of our business a great deal more thought than we have been accustomed to give it. It will not do to continue in the attempt to treat these workers as the German government has treated the German people, as though they were to be instructed without any voice in the matter, as though they were to be ordered, driven, and herded in industry without having anything to say about it. These things are not possible if we desire a stable, profitable industry.

Man-power is a new word in industry, borrowed from the war, but it is a good word and one which must be recognized in industry more thoroughly if we are to increase the efficiency of our industrial organizations, provide ourselves with a stable foundation of production capacity and make it possible to pass through the reconstruction period with a minimum of turmoil.

### Co-operation and Democracy in Management

It is a good sign of the times that the steel business, with its recognized reputation for intelligent business management, has indicated that co-operation and democracy must become live words in industrial management. It is an encouraging sign that these organizations have seen that the good industrial worker needs to be led, not driven, just as the soldier; and that morale can be better secured by an army of co-operation and understanding.

It is said that the high morale of the American Army is due to the co-operative feeling and good understanding that exists between the officers and men and that this has been established by the training and character of its officers.

These experiments, undertaken by large stable industrial organizations, indicate that we may hope for the same kind of an army of industry and consequently the same kind of industrial morale, with its economic invincibility.

This cannot be accomplished, however, by the work of a few isolated companies who have seen sufficiently the necessities of the case to take some action.

Neither is it to be expected that any one man or set of men will evolve, at once, a plan which will satisfy the case.

The subject is too large for that; it involves too many factors in human action which are little understood in industry and rarely studied.

It will necessitate the widest study on the part of all men interested in industrial management. It will require the deliberate removal of all the prejudices,

misconceptions and misunderstandings which have overlaid the subject until the real possibilities are well-nigh buried in the heap. It will mean a new knowledge of labor movements and a new understanding of men as such. It will necessitate a study of the matter, prompted by the desire for co-operative understanding which animates the officer in the army.

Above all, it calls for the widest interchange of thought and the most careful examination of all plans, with full and free discussion of their practical application.

Only the combined wisdom of the industrial leaders, studying the problem with the energy which has distinguished their study of operating problems, supplemented by the same interchange of ideas and results, will enable us to approach it in the way that its importance and imminence deserve.

# A Business Man's Views Regarding Trade Acceptances\*

A System of Business Based on the Principle of Good Credit—The Man Who Will Not Accept a Trade Acceptance Is Not a Good Customer to Sell—The Advantages Analyzed

By C. E. Crofoot

THE trade acceptance is not new to the world. We in the United States are simply behind the times in its adoption. England, France and Germany, as well as other European countries, have long used this system to great advantage, in connection with the use of the banker's acceptance, which latter we have used in this country in connection with our foreign trade for many years. The progress of the trade acceptance toward general adoption in the United States has been an outgrowth of the present war. Foreign bankers and business men visiting our country in the interests of business with the Allies soon after the outbreak of the war stood aghast at our antiquated commercial credit machinery and our unfamiliarity and apparent indifference toward so important an asset as the trade acceptance.

The first impetus given to the trade acceptance dates from the War Convention of American Business with the Chamber of Commerce of the United States, held in Atlantic City one year ago this month. At that great convention only subjects of national importance were discussed, bearing upon the relations of business efforts toward winning the war. Under the subject, "Banking and Finance," the trade acceptance was brought out from its obscure position in America in the past by prominent business men who, head and shoulders above their contemporaries, had tried out the method to their satisfaction and profit. In turn the prominent bankers in attendance indorsed the plan almost to a man in view of its opening up an almost unlimited field for extending banking operations. And so the present trade acceptance boom was launched, the rigging of the ship and its preparation for its publicity voyage being left to the joint

## The Advantages of the Trade Acceptance

*Does away with the open account.  
Provides a larger line of bank accommodations.  
Simplifies bookkeeping.  
Creates a better class of customers.  
Makes for increased profits by a quicker turnover.  
Prevents over buying and promotes careful attention to financing.  
Being two named paper is more readily discounted.  
Places credit upon a higher plane.  
Ties up less capital.  
Develops a keener sense of obligation.  
Insures more prompt attention to payments when used and in general tends toward the elimination from financial transactions of many of the elements of difficulty and annoyances which now embarrass them.*

care of the American Bankers' Association and the National Association of Credit Men.

Under the guidance of these two great American organizations a third came into being, the American Trade Acceptance Council, for the express purpose of furthering this great movement. In addition to the American Bankers' Association and the National Association of Credit Men, the Council is backed by the Chamber of Commerce of the United States and the National Asso-

\*Read before the Convention of the American Gear Manufacturers Association.

ciation of Manufacturers. What more influential support could it have? At a widely attended meeting held in Chicago last May, the council was addressed by Mr. Paul Warburg, Deputy Governor of the Federal Reserve Board, and from that time the movement has become general throughout the country through the wide publicity campaign of the National Trade Acceptance Council.

The purpose of this article is to aid through such publicity as it may extend to our members and thereby enlist the American Gear Manufacturers' Association in this movement, a movement that can only result in great benefit to ourselves as well as toward the cause for which we are all working to-day. While the association so far as I know has not as yet been asked to recommend the adoption of the trade acceptance method by its members, the advantages to be gained thereby are so obvious that we do not need to wait for any man. Let us take time and opportunity by the forelock and jump on the "Trade Acceptance Band Wagon" even without an invitation. I am sure we will be welcome.

#### Founded on the Principles of Good Credit

Let us consider just what the "Trade Acceptance Plan" is.

First, we must not forget that it is founded on the principle of good credit. It is for the man who pays his bills. If a man will not accept a trade acceptance, he is not a good customer to sell. We do not want that kind, and the sooner he is eliminated the better. Credit has been defined as "A promise to pay money or its equivalent at some future time"; also as "The power to get goods in exchange by giving a promise or contract to deliver an equivalent at some future time."

Now, then, the question is: What is the best form for that promise or contract to take? Shall it be the open book account or the promissory note or the trade acceptance? Let us see; most of us are now doing business, I venture to state, upon the open book account system. "Is it satisfactory?" "No, and why, because its principle is wrong." It has no foundation and cannot stand even the most superficial examination for merit. It floats upon thin air, settling with its disastrous effects upon the unwary. It requires constant watching with its attendant expense of time, money and energy, and this at a time when man power is at a premium. We have inherited this system from the old Civil War days, previous to which the bill of exchange, the forerunner of the trade acceptance, was in general use. These went out with that war which caused such a demoralization of credits that business went upon an almost strictly cash basis. In order to get cash, merchants and manufacturers had to give liberal discounts, which gradually became lower with the restoration of normal conditions, and then, as the discount rate got down to a par with the rate at which money could be borrowed at the banks, customers were loath to take advantage of the low discount rate, and the custom of taking 30, 60 and 90 days' time sprang up, and this now antiquated system still sticks to us to-day, notwithstanding its utter inadequacy to meet present demands.

#### The Futility of the Cash Discount

It is true, some of us offer now a cash discount for payment in 10 days, but how much is this really worth to us under the present system? Very little, when you stop to consider what you actually get out of it, that you otherwise would not get if you sold net 30. Those that take the cash discount in strictly 10 days are the customers of good credit who would abide by any terms mutually agreed upon at the time of sale. Others deduct

unearned discounts at anywhere from 15 to 51 days, which defeats the purpose of the plan.

You may laugh at a man expecting to get away with a deduction of 2 per cent 41 days after date of invoice, but in the face of stated terms 30 days net, 2 per cent 10 days we once had a customer, notice I say once, who tried to put one over on us like this: "All shipments on the 27th of the month and after will be considered as of the first of the following month. We take 2 per cent discount on the 15th of the month following shipment, providing goods are received in good order within 7 days from date of shipment."

This amounts to 2 per cent at from 51 days after shipment to any old time. We didn't swallow this, but I have no doubt somebody did and is still, as the firm is now in business and must get goods somewhere. The open account, as its name implies, is open and wide open, until it is paid. Open to what? Onslaughts of every description. Returned goods, cancellations, claims for delays, deductions for unearned discounts, shortages, and we are content to take what is left or can't help ourselves, one of the two. We've acquired the habit and are blind to new ideas and methods.

#### It's Hard to Accept New Ideas

To illustrate:

The story is told of a conversation between a magazine editor and a friend in a Chicago hotel. "Do you use shaving soap when you shave?" asked the friend. "Of course," said the editor; "that's a silly question. Everyone does." "I don't," said his friend. "It isn't necessary. A little water does the work better. It softens the beard quite as well and without lather it's easier to see where you're shaving." "You're just a plain ordinary garden variety of liar," said the editor. "You can't put anything like that over on me."

A year later the editor was making a trip from Chicago to New York. As he entered the sleeper wash-room in the morning he noticed a man standing in front of the mirror shaving. The man was not using soap. He moistened his strong, black beard with a little water and went merrily on.

"I'm interested," said the editor. "Don't you use soap when you shave?"

"Haven't for years," replied the man.

When the editor told the story he said, "For twenty-seven years I used soap when shaving because everybody else used soap, and I had to be hit in the head twice before I could get a common sense idea into my ivory dome."

"I shave every morning," he continued, "and I haven't used shaving soap for a year."

This story was retold some time later to three men at lunch. Two said it was darned nonsense. The third said he knew it to be true. "I use soap when I shave," he said, "because I like it, not because it's necessary. I was in the war both in Cuba and the Philippines," he said. "I couldn't get soap, but I always had as good a shave, although I didn't always enjoy it so much."

So much for the open account.

#### The Promissory Note

The promissory note has its place in business to-day the same as it always has had. The promissory note given by the debtor to the creditor can be made to cover any kind of business transaction or obligation. It is as frequently given for money borrowed for illegitimate use as for the legitimate; for speculation in the market or for the flotation of stock. Unless the maker of the note is favorably known to the creditor it is not looked upon with favor and sometimes not then. How many of us have not been touched up at one time or another by a

"friend in need," business or social, and eventually stung on his, of course, perfectly good note.

The trade acceptance does not propose to eliminate the legitimate or preferential use of the promissory note. It will, it is hoped, displace it in current transactions in merchandise as well as displace the open bank account. The trade acceptance was devised to represent current transactions in merchandise only, and as such I want to explain its advantages before our members to-day.

#### What Is a Trade Acceptance?

It is defined as "a negotiable certificate of indebtedness arising out of a *current* transaction in *merchandise*." Notice the emphasis on the words "current" and "merchandise." These are the distinguishing features of the trade acceptance as compared with a draft or promissory note, and are what gave it preferential standing with the banks. It is *not* to be given to cover a transaction of any other character or for a merchandise account past due! The nature of the transaction, therefore, becomes self evident and the paper by virtue of this is entitled to a special rate of discount.

It is true, discount charge must be borne by the seller, but he is glad to assume this for self liquidating paper promptly received in lieu of former losses by the old fashioned loose and expensive open account methods. Then, again, the trade acceptance is planned to be issued for short periods, 30 to 45 days at the longest, and dating from the date of invoice, so that discount is not heavy.

The trade acceptance transaction is completed after its issuance by the seller by its acceptance by the buyer. He writes his name across the face of the acceptance, together with the date and place of payment, and thus assumes the direct credit liability for the merchandise, title of which has passed to him. The transaction thus completes itself in so far as "proof of claim" is concerned and becomes self liquidating by giving the seller negotiable paper at the outset.

We now see that the trade acceptance takes care of a current merchandise transaction in a far better way than any other method, both from the standpoint of reliability and quick results both to buyer and seller. It has no disadvantages except to the old *skinflint*. As he would never accept one, we will let him worry.

#### How the Trade Acceptances Can Be Adopted

We can adopt the trade acceptance by either of two methods—by previous agreement or by persuasion. We can state our terms under the plan and refuse to sell under any other, or, we sell a concern a bill of goods. We forward invoice together with a trade acceptance drawn upon ourselves at 30 days and ask him to accept it and return to us promptly, provided he does not wish to take advantage of the discount to which he is entitled for payment in 10 days. We follow up with appropriate letters if he does not accept promptly, explaining the purpose of the plan and its patriotic and economic significance. We finally bring him around to the trade acceptance idea within the 30-day period, or, if not, our letters will have had a telling effect toward a settlement in cash long before we would have chased up a delinquent under the old open account system. Some concerns are offering 15 days extra time provided the trade acceptance is accepted, drawing same at 45 instead of 30 days. Undoubtedly other inducements will present themselves as the plan comes into general use.

Our concern is endeavoring to adopt the trade acceptance plan. We made a beginning last spring and have made some progress. Like all other reforms, the sledding is hard at first. The plan needs the help of every member of the A. G. M. A., and in standing to-

gether as one influential association, we can accomplish what we desire. In so doing we shall in no small measure help to put the finances of the entire country on a definite economic basis. If we are to whole-heartedly further the trade acceptance movement, we must stand ready to give as well as to receive.

The ball has been started rolling for us; let us get behind it with a will, and before another year goes by I am sure that we can point with considerable satisfaction to our column of assets, and, instead of dead ledger accounts 60, 90 and 120 days old, show trade acceptances at 30 and 45 days; negotiable assets which if we prefer to discount will represent just so much more cash on hand less the interest we shall all be willing to pay for the accommodation. But this ideal liquid condition cannot be attained overnight or without considerable effort on our part. When one thinks of it, why should we as business men finance our customers? That function belongs to the banks.

Let us consider the condition as of the banks on the one side and the business men on the other. We, the business men, buy and sell and cover our transactions immediately by trade acceptances. These trade acceptances will be handled for us by the banks if we desire, who in turn can re-discount them at the Federal Reserve Bank without question or limit. What condition could be more satisfactory than this liquid condition brought about by its being possible to realize immediately upon accounts as represented by trade acceptance?

#### A Needed Cog In Our Financial Machinery

The trade acceptance satisfactorily supplies the missing link in our financial system to-day. We are behind our allies in its adoption and extended use. In Germany it is interwoven in her almost perfect financial cycle. The question of financing the war gives Germany little concern. Her system was worked out years ago. Food, manpower and raw materials are her desperate wants to-day. Not on account of her lack of planning, but because we have fooled her for once. We finally woke up on preparedness. She figured we never would or could. On the other hand we must begin where she left off on matters of finance or suffer the consequences. We must be alive to the rapidly changing conditions on every hand to day. Never before has there been such an awakening in patriotic spirit on the part of the American people. Let us couple this with a broad vision by the business men into the requirements of the future. Let us not be behind our banking contemporaries. The establishment of the Federal Reserve Bank was the first great step toward the stabilizing of American banking.

The general adoption of the trade acceptance among the business men of America will be another important step forward toward the perfection of our financial machinery, thereby stabilizing business credit.

The time has come to make the use of the trade acceptance plan a national business custom. Our own protection compels it. Good business necessitates it. Patriotism demands it.

ACCORDING to *Electrotechnik und Maschinenbau*, special apparatus has recently been contrived to measure rapidly fluctuating temperatures such as an ordinary thermometer is too sluggish to record. At the point of measurement, wires of platino-iridium, 0.02 mm. diameter, are inserted and are connected to a galvanometer. The deflection varies with the resistance of the wires, and it is stated that variations in temperature with a frequency of ten per second may be noted. It is anticipated that the apparatus will be specially useful for studying cyclical variations in temperature in the cylinders of combustion engines.

# The Belt-Rail Creeper Tractor

—Engine and Transmission Form Power  
Unit Supported at Three Points—  
Spring Mounting for Front Ends

*Rear view of Belt-Rail tractor, showing spring stabilizers between axle and radiator frame*

illustrations that the center of gravity of the whole machine is very low, and it therefore has a high degree of stability. As already pointed out, the engine is the Waukesha BU4, which has a bore of  $3\frac{3}{4}$  in. and a stroke of  $5\frac{1}{2}$  in., giving it a piston displacement of 232 cubic inches. According to the rating of the engine manufacturer, this engine develops 40 hp. at 1650 r.p.m. It is of the unit power plant type, and the transmission casing is built integral with it. The whole assembly is mounted on the frame with a three-point support, there being a central swivel support at the forward end of the engine and two points of support at the rear end of the transmission housing.

## Runs on Gasoline or Distillate

A Kingston Model L carburetor is fitted, and either gasoline or distillate can be used as fuel. The fuel is carried in an 18-gallon tank, located in a rather high position directly behind the engine, and is fed to the carburetor by gravity. All air drawn in by the carburetor is passed through a Bennett air-cleaner. The speed is controlled by a Waukesha governor, built integral with the engine. Ignition is by a Dixie Model 46 magneto.

Water is the cooling fluid used, and is circulated by a centrifugal pump through the Sparks Withington radiator, the whole cooling system having a capacity of 10 gallons. The radiator core measures  $18 \times 21\frac{1}{2} \times 3\frac{1}{2}$  in. Back of the radiator is mounted an 18-in. fan, which is driven by a  $1\frac{1}{2}$ -in. flat belt.

**A** CREEPER tractor, differing materially in its creeper action from others of the same type, is manufactured by the Beltrail Tractor Co., St. Paul, Minn. The machine is equipped with the Waukesha Model BU4 engine, and has a rating of 12 hp. on the drawbar and 20 hp. on the belt. At a speed of  $2\frac{1}{4}$  miles per hour the drawbar pull figures out to about 2000 lb., so that the tractor should be capable of pulling three 14-in. bottoms under any conditions. The chief claim made for the Belt-Rail tractor is that the unit of pressure of the track on the ground is very low, and the tractor therefore can be used for working in soggy ground, where horses and wheel-type tractors would quickly become mired. Of the entire weight of the tractor only 28 per cent is on the front wheels and the remaining 72 per cent is on the belt-rail, the latter having such a ground contact area that the unit pressure is only  $3\frac{1}{2}$  lb. per square in.

It will be seen from the

*Power is applied to the creeper of the Belt-Rail tractor through large bull gears, meshing on top of the belt. Note cantilever springs for front axle*

Side view of Belt-Rail creeper tractor. Note air cleaner on carbureter, power pulley and bull gear drive on belt

The clutch, which is fully inclosed, is of the dry disk type, comprising three driving and two driven disks, the driving disks being faced with asbestos on both sides. In addition to the two driven disks, the cast-iron end plates, of which one is bolted to the tapered forward end of the clutch-shaft, and the other is adapted to slide along that shaft, also take some of the torque. Studs riveted into the fly-wheel web serve as the driving members, and the driven disks are treaded over spring bolts, which are riveted into the clutch flange. The fluted shaft of the transmission is supported at its forward end in a ball bearing in the flywheel flange. A ball thrust collar is used for the shifting lever.

The transmission affords two forward speeds, of  $2\frac{1}{4}$  and  $3\frac{1}{2}$  miles respectively, and one reverse speed, equal to the low forward speed. Power for the belt drive is taken off the forward end of the fluted shaft, through a pair of bevel gears. The shaft on which the two sliding pinions slide is the lower of the two in the transmission case. On the upper or secondary shaft there is a bevel pinion at the rear end, meshing with the bevel gear on a jack shaft. This same shaft, which is  $1\frac{15}{16}$  in. in diameter, also carries an 11-tooth spur pinion meshing with a 34-tooth spur gear on a parallel shaft. These two reduction gears, bevel and spur, are inclosed in the same housing as the transmission gears, though in a separate compartment. Hyatt roller bearings are used in the transmission, in conjunction with Bantam thrust bearings.

The final drive is through bull gears, which mesh with teeth on the outside of the belt-rail. There are two of these gears, one on either

side of the transmission case. The bull gears are  $22\frac{1}{2}$  in. in diameter. The width of the track is 21 in. and its length 48 in.

The belt pulley shaft is mounted in Hyatt roller bearings. The pulley is 10 in. in diameter, and has a width of face of 6 in. The gearing is such that at normal engine speed the belt speed is 2500 ft. per minute.

#### Track Rollers Adjustable for Wear

As in other creeper tractors, the weight of the tractor is supported on the track through a series of rollers, five in number. Of these rollers the two outside ones are adjustable lengthwise, so as to permit of taking up any slack in the track due to wear of the joints. The rollers for the track are of the spool type, and their shafts are mounted on Hyatt roller bearings.

The front axle is secured to the frame at the forward end by a sort of pivot and sliding joint; quarter elliptic cantilever springs are used between the frame and the end of the front axle, and there is also a radius rod

Horizontal section through transmission clutch and final drive

Rear and front of the Belt-Rail tractor, showing on the right the attachment of stabilizers to radiator frame

connection. What is known as a stabilizer consists of two coil springs, extending between brackets near the steering heads on the axle, and hooks secured to a frame surrounding the radiator. These permit of the track accommodating itself to sloping ground. The steering wheels are 36 in. in diameter, and are controlled through a screw and nut steering mechanism, operated by means of a hand wheel. The tractor has a turning radius of 9 ft. The frame is built up of 7-in. channel steel. The drawbar may be attached at two different heights, 11 and 18 in.

The weight of the tractor complete, without fuel or water, is 4500 lb.

### Special Threshers for Gas Tractors

ON a former occasion mention was made in these columns of how the advent of the tractor had resulted in changes in the design of such farm implements as plows and binders. Plows for tractors are made more rugged to stand the less yielding draft of the tractor, and in some instances they are made with more sloping mold boards to permit of higher

speeds than that attained by the plow horse. Binders have been made to cut a swath of 10 ft. so as to better utilize the power of the tractor without wasting man-power in providing operators for a number of binders hitched in tandem.

During the past year there has been a notable change in the demand for threshing outfits. Until quite recently it was the custom throughout the Middle West, as well as in some other sections of the country, to let out the threshing to contractors who owned steam power threshing outfits. These were large outfits with 36-in. or 42-in. separators requiring from 18 to 20 men to operate them. The contractor, however, furnished only three or four men, perhaps an engineer, a fireman and a water wagon driver, and the rest of the help was secured by neighboring farmers helping each other out.

In pioneer days this no doubt seemed the most economical method, but it has certain disadvantages. The task of boarding 18 or 20 men for two or three days is in any case a most arduous one for the farmer's wife, and is rendered more so by the uncertainty as to the arrival of the thresher, dependent upon weather conditions, breakdowns, etc. Also, when a large number of farmers use the same outfit, some will have to thresh when conditions are not propitious, as when the grain is wet or when it has stood so long in the shock that much is lost by "shelling out" in handling.

As a result of the conditions outlined, there has been a brisk demand during the past year for small threshers adapted to be operated by a three-plow "gas" tractor. It is natural that the farmer who has money invested in a "gas" tractor does not cherish the idea of spending additional money hiring a steam traction engine for his threshing. These small threshers are sometimes referred to as "individual threshers," because they sell largely to farmers for use on their own farms only, but in some cases farmers owning tractors and small threshers will do custom work for some of their neighbors, and in others several farmers in the same neighborhood will buy a thresher together. As only three or four men are required to operate these threshers, the difficulties experienced in accommodating the large thresher crews of former years are obviated.

It is the conviction of a number of leading implement men that the days of the large steam threshing outfit are numbered. The new small thresher is more convenient.

# Some Thoughts on Bombing Plane Engines\*

By a Foreign Expert

FROM the point of view of the pilot, reliability is a prime essential in an aeroplane, and to judge from results, the upright type of engine would appear to be considerably more reliable in the long run than the Vee type. One has only to look at the number of long distance raids undertaken by the enemy and the extraordinarily low percentage of engine failures to realize this. Simplicity is the keynote of efficiency, and incidentally reliability. Surely the following comparison speaks for itself. Take two typical English and one typical German engine of identical horsepower, the 250 hp. Rolls-Royce, the 260 hp. Sunbeam and the 260 hp. Mercedes.

	Rolls-Royce	Sunbeam	Mercedes
Number of magnetos.....	4	4	1
Number of ball races.....	22	17	1
Number of cylinders.....	12	12	6

The principal figures in the foregoing comparison, worthy of note, are the number of ball races. There is at present a serious shortage of a particular grade of steel necessary for the manufacture of ball bearings, which is likely to become acute in the future, so in designing the ideal engine it would appear to be necessary to cut down the excessive number of ball races,

\*While not agreeing with all the views expressed by the author, we print this article because it calls attention to some important truths.—Editor.

as in the Mercedes. The Sunbeam and the Rolls-Royce are high speed, high compression engines, while the Mercedes is a low revolution and low compression engine. Yet which has proved the more reliable under active service conditions? Undoubtedly the Mercedes. What is most needed in an aeroplane is a "margin of power." No automobile engine could be expected either to run reliably or to last any lengthy period of time if it were constantly run on full throttle. The principal reason for its reliability lies in the fact that it is constantly running at different speeds, and seldom on full throttle for long. (Of course, I realize that a car engine has many advantages over the aeroplane engine, as regards solidity and strength of build, but the foregoing is the principal cause of its reliability.)

So far no aeroplane engine has been built or even designed which pretends to yield this much-needed "margin of power," least of all the Vee types. Unless they are running practically "all out" the difficulties of carburetion are such that the engine does not fire evenly on all cylinders. Colloquially stated, no Vee type engine will "tick over" evenly at a slow speed for long, and until an engine is designed which gives this "margin of power" it is not worth while any firm taking up the question of aerial transport from a commercial point of view, because engine failure will remain more or less a lottery. Of course the present type of aeroplanes could be used (with slight modifications), perfectly easy for commercial purposes, but the profits would be totally inadequate even to defray expenditure in overhauls, crashes, etc., or the prices would have to be made so excessive that nobody would take it up.

## Reliability Better Than Speed

Now that we are proposing to undertake the bombing of German towns on a large scale, reliability will be more of an essential than speed, and yet nearly every engine designer persists in designing these high efficiency multi-cylinders, short stroke, high revolution engines, which can only be compared to a racing car. The specialized racing car is tuned up for one race and for one race only, and if that race happens to be a long one, it very often happens that the car is of little use for anything else afterwards because it has been "driven to bits." If you wanted to make a long journey as quickly as possible by road, which would you choose, the specialized track racing car or the high-powered roadster? Undoubtedly the latter,

Ammunition stores and batteries as seen from an Allied airplane over German lines. This photograph reveals clearly a 21-c.m. howitzer gun in the open. With this photograph and the aid of an air observer an artillery commander can quickly demolish the gun

use, though not capable of such high speed as the ; it would prove to be far more reliable under adverse conditions. Similarly, if you wanted to travel a distance over hostile territory and were well equipped, speed would not matter to nearly such a great extent as the staying power of your engine. For an engine to be reliable it must be simple in design, and it has to run constantly at the same speed the revolutions per minute must be low.

#### Success Depends on Pilot's Morale

There is another point which seems to have escaped the notice of a great many of the present-day engineers and that is that the success of an expedition largely depends on the morale of the man who pilots the machine. If this man knows that his engine is going to let him down, that it is reliable, he will have a greater chance of making a success of his raid than if he is constantly waiting and listening for the revolution to slacken down. He knows of no worse feeling on this earth than to be piloting a machine behind an enemy that is known to be unreliable over hostile territory, and to be living in fear of engine failure. Some one imagines that one hears strange sounds in the beating of the exhaust. All the time one is constantly keyed up and listening for things of this nature, with the result that after a time you begin to hear things which don't really exist and eventually, if you use this type of machine long enough, your nerves give away altogether.

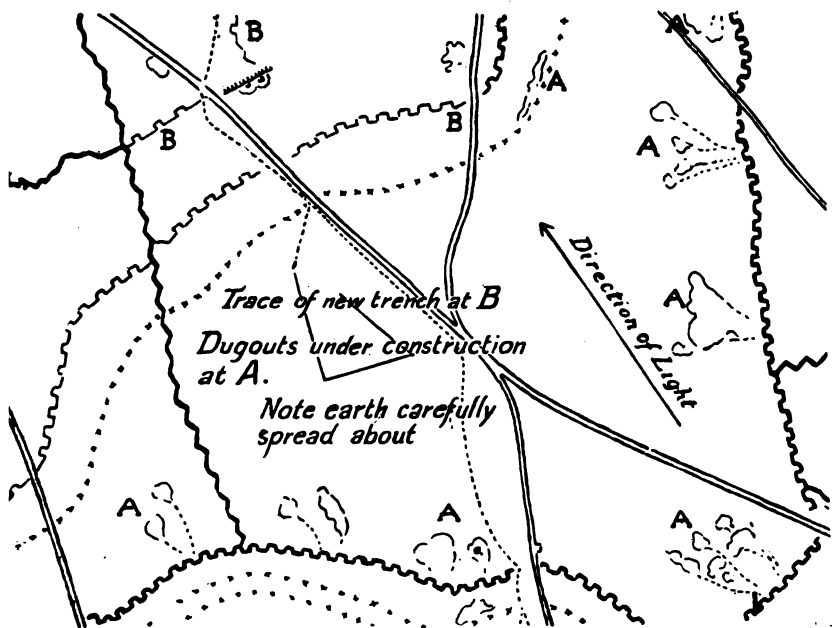

Again, there is another point which is worthy of note, and that is that no Vee type water-cooled engine has ever run for nine consecutive hours in an aeroplane. In engines of this type, unless accurate balance is maintained, the vibration becomes tremendous, and

even when the engine is running sweetly, the vibration which extends to all extremities of the machine is quite considerable.

What are the principal advantages of the Vee type engine over the upright engine in car design? Simply that you get one explosion for every quarter revolution of the roadwheel, together with great rapidity of acceleration, neither of which is of the slightest use in an aeroplane.

Some of the points in favor of the upright engine are ease of over-haul, facilities for rapid production, no duplication of fittings, reduction of head resistance, in most cases direct drive. Above all this the Vee engine is only in its infancy and is just beginning to be adopted by car designers, and will have to run the gamut of many alterations and improvements before it is finally, if ever, adopted.

## Making War Maps by Camera

The above view, taken from an Allied airplane over the enemy lines, shows clearly the importance of air photography for the detection of new trenches and dugouts under construction. The method of detecting the important points in photographs is illustrated by the diagram, which is the result of tracing from the photograph the objects worth investigation and study without the confusion of the unnecessary details. For example, near the trenches marked A the enemy has thrown up considerable ground to create confusion to observers. This soil, however, indicates dugouts under construction. The new trenches, marked B, are known by the absence of the heavy shadows which mark the deeper finished trenches.

# The Pfalz Single-Seater Fighter

## Part V

### Attachment and Construction of Inter-plane Struts and Compression Tubes— Mounting of Armament

THE top plane of the Pfalz is supported from the body by two inverted, flattened U's, as mentioned and illustrated in our last issue. The attachment to the top plane is of a similar character, as shown at the top of the following page. The upper corner of the center-section struts is provided with a sheet steel shoe to which is welded a socket or cup. A bolt passing vertically through the spar terminates in a ball-shaped head, which fits into the cup, and a taper pin passing through ball and socket locks the joint. The inter-plane cables

*A steel tubular crank lever made from two halves welded together along the seams is used for operating the ailerons on the Pfalz*

are attached to little anchor pieces shaped as shown in the sketch, terminating inside the larger cup in a wide head shaped to fit the internal curve of the cup. A certain amount of play is therefore allowed. The right-hand sketch in this illustration shows, from a different point of view, the corresponding fitting on the rear spar.

The internal compression tubes of the wings are secured to the spar by a very simple fitting, shown in the inset sketch. A small steel plate is stamped out to form a shallow projection, the diameter of which corresponds to the internal diameter of the compression tube, which is thus prevented from slipping on the spar. This sheet steel plate is secured to the spars by two horizontal bolts, and its ends are shaped to form the lugs for the attachment of the drift or anti-drift wires, as the case may be. The drift wires of the Pfalz are in reality tie rods of circular section, threaded at their ends to fit directly into the barrel of the turnbuckles. The anti-drift wires are solid wires of about 12 gage size.

#### The Inter-plane Struts

The inter-plane struts of the Pfalz are approximately of Vee form, although they do not quite come to a point at their lower ends. In section they are, needless to say, stream-line, and constructionally they are built up of various laminations, as illustrated herewith in section. The two outer layers are spruce. Then come, one on each side, two layers of three-ply, while the center of the strut is formed by a piece of spruce. The whole is then covered with fabric. The same construction is employed for the center-section struts. The angle formed by the vertical and horizontal arms of these struts is elaborately built up of laminations, the grains of which cross one another at various angles. The strength appears good,

but the struts are certainly not light, compared with the ordinary hollow or even solid spruce strut.

The attachment of the inter-plane struts to the bottom plane is interesting. As the horizontal arm of the struts is shorter than the distance between the spars of the bottom plane the struts cannot be attached directly to the spars. Instead, they are attached, by means of the usual Pfalz ball-and-socket joint, to a compression tube. Owing to the fact that this tube is subject to a lateral load, being loaded both as a strut and as a beam, the usual compression tube attachment already referred to would be inadequate. Instead, the arrangement shown at the bottom of this page is employed. The compression tube is unlike those used elsewhere in the planes, inasmuch as it is not of circular section, but is flattened so as to have flat parallel sides and a top and bottom forming arcs of a circle. At its ends this tube is welded to a base plate of channel section, which partly surrounds the three sides of the wing spar. Before being welded to its end plates the tube is slotted at its ends to accommodate the lugs for the drift and anti-drift wires. These lugs are formed by bending a piece of sheet steel to a channel section, the bottom of the channel being welded to the base plate and the arms welded to the compression tube. The horizontal bolts securing the base plates to the wing spar have their heads filed flat so as to pass between the two drift wire lugs, and are thus at the same time prevented from turning when tightening up the nuts on the other side of the spar. The details of this part of the wing will be clear from the illustration.

The general arrangement and spacing of the wing ribs of the Pfalz were shown in our last issue. Construc-

tionally the ribs are built up in the usual way of three-ply webs and spruce flanges. False ribs occur between the main ribs, running over the top of the spars, from leading edge to rear spar. These false ribs are made of ash. In connection with the main ribs mention may be made of a rather neat arrangement for attaching the ribs in place on the spars. As usual the rib-flanges are tacked to the top and bottom faces of the spars. In addition the ribs are prevented from sliding along the spars by two vertical pieces of wood, each tacked to the spar. In the middle these vertical pieces are slotted to accommodate a small square block of wood about  $\frac{1}{2}$  in. square—which is glued to the face of the spar. The end of the rib web is recessed to give room for this block, the effect of which is, it will be seen, to relieve to a certain extent the shearing stress on the rib flanges at the corners of the spar. It is only a small detail, but it is worthy of mention, and has been included in the large illustration herewith.

The crank lever of the ailerons is shown in another of  
(Continued on page 604)

*Details of the steel compression tubes and the attachment of the tie-wires on the Pfalz*

*The V-form inter-plane struts are mounted on a steel cross-tubular member, as shown above. The struts themselves are of laminated wood as indicated in the section. The small insert in the corner shows the method of attaching the wing ribs to the spars*

## HORSELESS AGE SUBSCRIBERS

Subscriptions for the Horseless Age transferred to the subscription list of AUTOMOTIVE INDUSTRIES in the merging of the two publications will be completed in full by the weekly issues of AUTOMOTIVE INDUSTRIES to the dates of expiration shown on the records of the Horseless Age Co.

Owned by United Publishers Corporation, Address 243 West 39th St., New York; H. M. Swetland, President; Charles G. Phillips, Vice-President; W. H. Taylor, Treasurer; A. C. Pearson, Secretary.

Entered as second-class matter Jan. 2, 1903, at the post-office at New York, New York, under the Act of March 3, 1879.

Member of the Audit Bureau of Circulations.

Automotive Industries-The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repair man (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907.

## The Desirability of Parachutes for Airplanes

EVERY seagoing vessel carries its life boats to which the passengers and crew may repair in case of shipwreck. A life boat is not an absolute protection to the sailor, yet it is the means of saving a large proportion of those who would perish at sea if no such safety devices were carried.

When an airplane is seriously damaged while in flight the occupants are in about the same predicament as the crew of a foundering ship without life boats. The thought has naturally occurred of equipping airplanes with parachutes, which would enable the aviators to jump and descend safely to earth in case the machine took fire, became uncontrollable or was badly damaged by enemy gunfire. Parachute descents from balloons have been made for a great many years and the development of a reliable parachute should in itself not present any insuperable difficulties.

Of course it must be light and compact, so it does not detract too much from the speed, climb and ceiling of the machine. Probably one of the most difficult engineering problems connected with the proposition would be that of a reliable method of attachment to the plane.

### British and German Experiments

Many times in aerial combat aviators are seriously wounded and would not be able to take advantage of a parachute carried "on board," yet it is felt that a device of this sort would save many lives, and after it had once proven its efficacy its presence on the machine would tend to save the nerves of the occupants. The subject of parachutes has received widespread attention in the British press of late, but as yet no steps seem to have been taken to provide them on British war planes. A recent unsuccessful demonstration, which resulted in a fatality, may have the effect of retarding the adoption of the device, though the accident is said to have been due to fault in the attachment and in no way to the parachute itself.

On the other hand, the Germans have begun to equip their fighting planes and recent advices from the British front in Flanders record two escapes of aviators from Fokker biplanes shot down by the British. It would appear from the description given that the device functions automatically, filling with air in consequence of the quick fall of the plane and pulling the aviator out of his seat. If safe landings were effected we will no doubt soon see parachutes made regular equipment of all war planes.

## The Eight-Hour Day as a Basis for Wages

IT is considered probable that practically all of the large steel producing organizations will follow the lead of the United States Steel Corporation in the adoption of the 8-hour working day for employees.

The 8-hour day is the goal for which the working man and labor union have been striving for many years. It has become a sort of fetish which the laborer has worshipped. Whatever conception he had of it and its advantages at the beginning of his fight for it has been modified during the long process of evolution which has been necessary to bring big business, as typified by the Steel Corporation, to a realization of the justice and advisability of granting it now.

What the working man gets, in this case at least, is not an actual working day of 8 hours but a day of that length which is used as the basis of computing his pay. The actual 8-hour day could not be granted now and the laborer understands why. He knows as well as any one that production cannot now be allowed to fall off. He will continue to work 10 or 12 hours a day, as he has during the recent past, and a cold calculation in the accounting department will show that he will be getting for his efforts what is in reality a wage increase of less than 10 per cent.

## They Are Not Buying Liberty Bonds in Belgium

**T**HE manufacturers of Belgium and Northern France are not buying Liberty Bonds.

Some of them are paying tribute to the Hun at a rate which makes our excess profits tax look like a miser's contribution to the village poor-box.

Those who are not paying tribute have already paid the ultimate price of all victims of the Great World Monster—complete annihilation.

The difference between the Belgian manufacturer and the American manufacturer in this respect is merely a difference of distance from Berlin.

We know this now.

We know, too, what the Hun is and what he tried to do.

We know what his methods are and what he thinks of human rights and human life.

We know his ideas of liberty.

We know our duty at this particular time and we will do it.

\$6,000,000,000 worth of Liberty Bonds must be sold—will be sold before the end of another week. The time for explaining why we should buy these bonds has passed. No explanation is now necessary. Everyone knows now not only that it must be done but that it is the one and easiest thing to do.

Everyone knows now that a Liberty Bond, if it paid no interest and never would be redeemed, is still the best investment ever offered in the history of the world, measure its value in any way and by any standard you may choose. Everyone knows this now, Mr. American Manufacturer, you and all of your employees, down to the most unimportant one among them. You need *not* to sell your helpers Liberty Bonds. You need merely give them the opportunity to buy them. And you will do it.

Whether or not yours is a 100 per cent organization depends wholly upon what steps you take to make it so.

And keep this in mind. It is most fortunate that you and your employees do not have to *give*. It is the glorious privilege of both of you to *lend* as our fighters fight.

## Truck Plans of Car Makers Halted

Government Ruling on Starting Industries Brings Change—Several Affected

DETROIT, Oct. 1—Many passenger car manufacturers in this territory who some time ago announced their intention of entering the truck manufacturing field are obliged to change their programs owing to the Government's ruling relative to starting of new projects.

Among those affected in this territory are Paige, Oakland, Willys-Overland, Olds, Briscoe and Columbia—all passenger car builders. All of them went to more or less expense in preparing their plants for the production of truck models and now must lay aside these activities at least until the war is over. They will all concentrate their efforts on war work.

Nearly all these affected manufacturers, however, will preserve their plans—just stop where they are now—and as soon as the Government gives the word "go" it is their intention to continue from where they left off.

Practically all the truck manufacturers here are on government work—that is, very little of their production is going to commercial fields. The Federal has no trucks going to its dealers.

### Chandler Delivering Tractors

CLEVELAND, Oct. 2—The Chandler Motor Car Co. has reached quantity production on its 10-ton artillery tractors and has delivered 100. It is expected that monthly deliveries will increase rapidly and that 1000 tractors will have been turned over to the Government by Jan. 1.

### Paige Nearly 100 Per Cent on War Work

DETROIT, Oct. 3—The Paige-Detroit Motor Car Co. is rapidly nearing 100 per cent war work and will soon be in production on kitchen trailers, depth bombs and ordinary bombs. This, with the additional order for \$3,500,000 worth of Quad trucks and work on the order for 2000 Signal Corps trucks, will put the company on a 100 per cent war basis in 60 days. Car production is now averaging 25 daily.

### Bomber Makes 143 M.P.H.

WASHINGTON, Oct. 2—A De Havilland 9 plane equipped with a Liberty engine flew from the McCook Field, Dayton, Ohio, to Bolling Field, Washington, D. C., with no stops in 3 hr. 5 min. The

actual flight from Dayton to Washington was 2 hr. 5 min. The distance between the cities is 430 miles with the time of flight 143 m.p.h. The journey was made by Caleb Bragg, civilian pilot, attached to the Engineering Department of the Bureau of Aircraft Production. An engineering officer was the passenger. The pilot traveled by compass at a high altitude and reported no difficulty in holding the course. The plane left for New York this afternoon and will start tomorrow or Friday on a non-stop flight from New York to Dayton.

### Flight Tests of Caproni Plane

WASHINGTON, Oct. 2—Flight tests of an American built Caproni airplane equipped with three Liberty engines are being held by the Bureau of Aircraft Production. A Caproni plane of this type arrived here to-day at Bolling Field from Hazelhurst Field, Mineola, L. I., and will leave to-morrow in a flight for Dayton. This Caproni is one of a few built in United States Government factories for test by American aviators and engineers. The tests are now being made in flights from various fields and will continue to be made until it is decided whether or not to put this particular type of plane in quantity production.

### Daily Liberty Output Averages 278

DETROIT, Oct. 3—Special to AUTOMOTIVE INDUSTRIES—The production of Liberty engines in the several plants that are carrying on this work is rapidly increasing and during the month of September the total average daily production reached 278. It is expected that during the month of October the total output will touch 3000 complete engines.

The Ford Motor Co., is the first plant engaged in this work to exceed a production of 100 complete engines in any one day; on Sept. 30, 120 engines were turned out. This number is increasing daily. Several of the plants, namely, Lincoln, Ford and Nordyke & Marmon, exceeded their August estimates.

### Quantity Liberty Engine Production Reached

WASHINGTON, Oct. 2—The output of Liberty airplane engines is fully up to expectation and has reached quality production. Airplanes are now going ahead rapidly and are being shipped in train load lots daily. These statements were made by W. C. Potter, Acting Director of the Bureau of Aircraft Production, following his return from an inspection of the factories turning out the planes and engines.

## Production Situation Clarified

War Board Has Talk with Makers of Cars and Trucks

NEW YORK, Oct. 3—Chairman Charles C. Hanch of the Automotive Products Section of the War Industries Board attended a meeting of the National Automobile Chamber of Commerce here to-day, and at its close the atmosphere was considerably clarified.

He made a long address before the manufacturers and repeated the statement that every effort should be made to get on a strictly war basis by the end of the year and that the factories may have until Jan. 1 to clean up their inventories. Sentiment among the manufacturers, however, is that they will be permitted to continue this cleaning up after Jan. 1, in case they do not get the job done before and that there is a possibility that the dealers will get some cars during at least the early part of 1919. The production of parts will continue. In cleaning up inventories the ruling of some time ago stands, that production during the last half of this year must not exceed 25 per cent of 1917.

Of the 117 members 74 are now on war work, ranging from 25 to 100 per cent.

Hanch also took up the truck matter. Some time ago it was ruled that makers could produce during the last half of 1918 one-third of the production of the preceding 18 months. Some makers have, however, made this amount during the last 3 months, which would seem to shut them down entirely under the ruling. Hanch stated, however, that such makers would go on at the same ratio as allotted, but that this excess would be deducted from their 1919 allotment.

The traffic committee cited these figures as to carload shipments: August, 1917, 22,000; August, 1918, 13,631; September, 1917, 20,538; September, 1918, 12,000.

The members expressed themselves as in favor of any taxation which is not discriminatory.

One hundred companies were represented by 128 men, one of the largest meetings ever held.

### Olds Will Make Liberty Engines

LANSING, Oct. 1—The Olds Motor Works will soon start production on its initial order of Liberty engines. The first lot of 2000 kitchen trailers is expected to be delivered during this month. The production of passenger cars is slowly being diminished and the plant will be entirely on war work by Jan. 1.

## 16 De Havilands Daily to France

First Plane Reached France in  
May—Make 130 M.P.H.—  
Praise Liberty Engine

WASHINGTON, Oct. 1.—From 15 to 18 De Haviland 4 airplanes, equipped with Liberty engines, were arriving daily in France in August, according to Major General William L. Kenly, Chief of the Department of Military Aeronautics, who quoted a captain of the Air Service just returned from the headquarters of the American Expeditionary Forces. The captain, stated General Kenly, reported that the first De Haviland 4 planes with Liberty engines arrived at stations in France as early as May 13, 1918, and since that date have been coming in increasing quantities. The captain said that it had been necessary to make some changes in the first planes received, but that each succeeding shipment showed better care, and when he left France the airplanes were very satisfactory. In his report the captain stated:

### Plane Popular With Pilots

The performance of the planes was very good and the plane and motor has become very popular with our pilots. We obtained approximately 130 m.p.h. at ground level with one plane and had without any special preparation obtained an altitude of 10,000 ft. in 10 min. 21 sec., full load, excepting bombs. We were able to loop, dive and otherwise stunt these planes exactly as well as we would any chase plane.

When I left the post the planes were arriving at the rate of 15 to 18 per day. The cars were unloaded by our steam crane, and fuselages unpacked in one day (platform), wings in another day and assembly was progressive, similar to the method used in automobile construction.

After gun test, engine test, and final assembly, the compasses were tested and corrected for permanent magnetism. The machines were then sent to the flying field and were given test flight. After final approval they were then dispatched to stations for assignment to squadron.

Air-test pilots and ferry pilots were all of the opinion that the plane was excellent. The French ministry thought so well of the Liberty motor that the Under Secretary of State for Aviation, Monsieur Dumesnil, informed me that the French would gladly take every motor we could produce which we could not use ourselves. I was also given the same information by Captain de Haviland, the designer of the de Haviland plane.

Lt.-Col. Warwick Wright, Royal Air Force, stated to me that the method of packing the plane was considered by the British to be so good that it could not be improved upon. Out of 750 cases which I inspected I only discovered one in which the contents were badly damaged.

## Implement Makers Get Price Concession

CHICAGO, Oct. 2.—Members of the National Implement and Vehicle Association have been given a concession amounting to approximately \$5 per ton in the price of iron and steel for manufacturing farm implements. The concession is to apply on shipments made on and after July 15, 1918, and on contracts made for material to be used in the ordinary farm implement season ending June 30, 1919. The concession covers steel bars and bands, cold rolled and cold drawn steel, and the following agricultural steel: Parallel shares and regular mouldboards (soft centers); O. H. solids, slag; special O. H., slag; disks, harrows and cultivators; coulters, 15 x 5/32 in.

## Doubles Reduction Drive for White 3 and 5-Ton Trucks

CLEVELAND, Oct. 2.—The White Co., which for some time has used the double reduction gear principle in the drive of its 1½ and 2-ton trucks, has applied this principle to revised versions of its 3 and 5-ton vehicles, in which it has also made a number of other improvements. In these two heavier models there is now employed a unit power plant which is an evolution of the White block engine; a cast radiator of the vertical tube type with removable head and a new system of brakes. Deliveries will be started as soon as factory production overtakes urgent military demands. The type of double reduction gearing employed is that in which the first reduction is obtained through a bevel gear and drive pinion in the center of the axle and the second reduction through drive pinions at the ends of the floating live shafts meshing with ring gears inside the hub case of the rear wheel.

## Lewis Vice-President of Pennsylvania

JEANNETTE, PA., Oct. 2.—Seneca G. Lewis has been elected vice-president as well as general manager of the Pennsylvania Rubber Co. Major C. M. DuPuy, who is at present in France, retains his title of vice-president, sharing this office with Mr. Lewis.

## Chalmers Stock Reduced \$660,000

NEW YORK, Oct. 2.—All the retiring directors of the Chalmers Motor Co. were re-elected at the annual meeting of the company held yesterday in New York. The stockholders approved the plan to reduce the common stock from \$7,060,000, consisting of 532,000 shares without par value, to \$6,400,000, consisting of 400,000 shares of common. The 132,000 shares which are cancelled are held in the treasury. No change was made in the preferred stock.

## Increase Oil Output 2000 Bbl. Daily

By Cementing 50 Wells a Saving  
of 750,000 Bbl. a Year  
Will Be Effectuated

WASHINGTON, Sept. 30.—By cementing oil wells in the North Cushing field of Oklahoma, thereby keeping out the detrimental flow of water, production of oil in the 50 wells has been increased 2000 barrels a day.

The experiment was made by the Bureau of Mines, Department of Interior. In addition to saving 2000 barrels daily for war uses, the experiment added \$4,500 daily to the operators' gross income, and if the increased oil yield continues for one year, which is a reasonable expectation, the experiment will have added 750,000 barrels of oil to the production and \$1,640,000 to the income of the operators.

The cost of cementing the 50 wells was \$10,000, which, when compared with the return, means \$165 for each dollar invested. The Bureau of Mines plans to introduce this new system of cementing the wells in other fields throughout the country in order to meet a possible oil shortage. Commenting on the report, Secretary of the Interior Lane said:

This is the kind of practical conservation that counts heavily just now. It not only is saving from waste one of the most precious natural resources with which this country is blessed, but is also supplying much needed fuel for the Army and Navy. At the same time it is paying the operators handsomely to increase the flow of their wells.

It happens that the crude oil from Oklahoma contains much gasoline. An increase of 2000 barrels of crude oil a day means 500 barrels of gasoline a day or more than 7,500,000 gal. in a year's time. This saving alone, from this restricted field in Oklahoma, is sufficient to drive every automobile in the United States an average of 20 miles, and there are 5,500,000 automobiles in the country.

The best of it is, this is but the beginning of an enormous saving of crude oil by keeping the water out of the wells. It has taken the bureau 2 years to demonstrate the feasibility of using cement in the Oklahoma wells, but now that such a saving can be effected it is being adopted by all progressive oil men.

I understand that the bureau has already started a campaign in the Healdton field, Okla., and that, while it has not yet received a report of the actual results, it is estimated that the saving in this field amounts to more than 300 barrels of crude oil a day. In Illinois the same plan is being introduced, so that the Bureau of Mines is confident that the total savings to the country will be considerable and will go quite a distance in supplying our urgent war needs.

## New Type Kerosene Carbureter

Applied to Any Engine, Gives Same Power as Gasoline Without Smoke or Carbon

NEW YORK, Sept. 28—A kerosene carbureting device which operates on a new principle, and which enables any internal combustion engine designed for gasoline to generate without any change whatever the same power on kerosene as on gasoline, without smoke, carbon deposit or dilution of the crankcase oil has been perfected and is being placed on the market.

The device is the invention of Enoch Rector and is to be manufactured and marketed by the Rector Kerosene Carbureter Co., which is already producing in a limited way and is at present negotiating for the production of the device in large quantities. James F. Allen, of J. F. Allen & Co., 111 Broadway, New York, a firm of bankers, is head of the company. Associated with him are: Vice-president, E. J. Ludington, president of the Chase Bag Co., St. Louis; secretary and treasurer, Stephen N. Bond; George Wilson, manager of the Union Bank of Canada; Archibald R. Watson and other bankers.

The device has been under development for more than a year, and in that time has been extensively tested in the laboratory of Joseph Tracy both for those interested in the company and the United States Government, the latter tests having been made in Tracy's capacity as consulting engineer to the Bureau of Oil Conservation. A long series of road tests have also been made, including the operation of a 5-ton Garford truck for 6 months with the device. The Fifth Avenue Coach Co., which operates the buses on Fifth Avenue, New York, has been experimenting with one of the devices, and during the past 10 days has operated one of its vehicles in regular passenger-carrying work.

According to the tests which were made by Tracy the Rector carbureter gives practically the same mileage on kerosene as can be obtained on gasoline. In laboratory tests the same maximum horsepower is obtainable and the curve shows a considerable increase in horsepower at all speeds below maximum. Analyses of the crankcase oil after both high-speed and low-speed runs show no measurable dilution of the oil. Smoke is completely eliminated, and in the case of the 6 months run of the Garford truck, there was only sufficient carbon deposit to warrant its being wiped off the pistons with a cloth; the valves were in excellent condition.

According to the tests which have been made, the flexibility operating on kerosene is indistinguishable from that obtained with gasoline.

But one size carbureter is required for engines varying in capacity from 15 to 75 horsepower.

In the conduct of the various tests it

is worthy of note that heavy vehicles carrying their rated capacities have always been used. No experiments have been carried on with light vehicles, the thought being that if the device would operate properly and efficiently with a heavy vehicle it would work equally as well with a light vehicle where the demands are not so severe.

Although the use of a heavy vehicle might presuppose almost a continuous capacity load on the engine with little variation of speed and few stops, the reverse has been the case. The device in use on a Fifth Avenue bus, for example—it is fitted to a Knight engine—is subjected to wide demands regarding speed variations with frequent stops of varying length. That the carbureter has equalled expectations for this work is evidenced by the fact that the Fifth Avenue Bus Co. is desirous of equipping all its fleet with Rectors. The fuel consumption measured in dollars and cents is about one-third that with gasoline.

Following are extracts from the report made by Joseph Tracy in his capacity as consulting engineer to the Bureau of Oil Conservation. The tests were made on a 10-ton Garford tractor chassis having a four-cylinder 5.1 x 5.5 engine equipped with Bosch magneto. The vehicle with load weighed 15,275 lb.:

On gasoline the "motor stalled at 9.05 a. m. at 42d Street and 10th Avenue; started immediately. Stopped 9.56 a. m. to telephone and started again at 10.06 a. m. Arrived at Yonkers on first trip 10.25 a. m.; arrived at 42d Street at the end of first trip at 11.30 a. m. Turned and resumed run without stopping. Stopped for traffic at 42d Street and Tenth Avenue one-half minute. Arrived in Yonkers on second trip at 12.34 p. m. Stopped at 12.44 for three minutes for drink. Finished second run at 42d Street at 1.43 p. m. Odometer reading at this point 2723.

"Before beginning third trip, one-half gallon of medium Polarine oil was poured into the motor crankcase. Started third trip from 42d Street at 2.15 p. m., odometer reading 2723 miles. Arrived Yonkers 3.18 p. m.; arrived at 42d Street at 4.20 p. m. Started on last trip at 4.23; arrived Yonkers at 5.23 p. m.; finished 6.27 p. m. at 42d Street, odometer reading 2779 miles.

"Summary of results:

"Weather: fine and clear.

"Temperature: average 73 degrees Fahr.

Barometer, average 30.16 in.

"Condition of road surface during test: dry and in good repair.

"Total distance traveled: 113 miles.

"Elapsed time: 9 hrs. 23 min. 30 sec.

"Actual running time: 8 hr. 35 min.

"Speed, m.p.h.: 13.1.

"Quantity of gasoline in tank at start: 25.375 gal.

"Taken from tank at finish: 3.375 gal.

"Used in test: 22 gal.

"Miles per gallon: 5.1.

"Ton miles per gallon: 39.19."

Immediately following the tests with gasoline, the same route was covered the same number of times with kerosene using the Rector carbureter. Following are the results:

"Weather: fine and clear.

"Temperature: average, 78 degrees Fahr.; barometer: average, 30.04 in.

"Condition of road surface during test: dry and in good repair.

"Total distance traveled: 113 miles.

"Elapsed time: 11 hr. 12 min.

## New Regulations for Exports

Licenses Regarded Used Within Period of Validity—Supersede All Others

WASHINGTON, Sept. 27—New regulations governing the expiration dates of export licenses have been effected by the War Trade Board. On and after Sept. 30, 1918, export licenses will be regarded as used within the period of their validity:

(A) If the through export bill of lading is issued and signed on or before the expiration date of the license and subsequent to Oct. 9, 1917; or

(B) If the ocean bill of lading is dated on or before the expiration date of the license; or

(C) If the dock receipt is dated on or before the expiration date of the license and the ocean bill of lading covering the same shipment is dated not later than 30 days after the expiration date of the license; or

(D) If the railroad notice of arrival issued at the port of exportation is dated on or before the expiration date of the license, and if the ocean bill of lading covering the same shipment is dated not later than 10 days after the expiration date of the license, provided that the provisions of this paragraph (D) shall apply only when the merchandise is exported on vessels loaded at railroad docks, where dock receipts as provided in paragraph (B) cannot be issued by the vessel or its agents; or

(E) If the shipment is on a lighter which arrives on or before the expiration date of the license, alongside the vessel upon which the shipment is to be loaded, and if the shipment is, in fact, loaded on that vessel and ocean bill of lading is signed not later than 30 days after the expiration date of the license.

The railroad agent issuing a through export bill of lading (combination rail and steamship bill covering goods to destination) will forward to the Bureau of Exports, War Trade Board, Washington, D. C., one copy of such bill of lading after there has been noted thereon the port of exit through which the shipment will pass.

These regulations supersede those announced in W. T. B. R. 152, made public June 29, 1918.

"Actual running time: 9 hr. 11 min.

"Speed, m.p.h.: 12.3.

"Quantity of kerosene in tank at start: 25.375 gal.

"Quantity of kerosene taken from tank at finish: 4.25 gal.

"Used in test: 21.125 gal.

"Miles per gallon: 5.3.

"Ton miles per gallon: 39.19."

The present development of the carbureter has only gone as far as kerosene. However, it would seem that other fuels might well be used, such, for example, as distillate, certain grades of fuel oil and crudes not having an asphalt base.

# Liberty Planes Are Being Rushed to Europe

First One Reached Battlefront May 18, and Others Have Followed at Rate of Five to Ten a Day Since

WASHINGTON, Oct. 1.—The first Liberty engine equipped airplane shipped from this country to France arrived on May 18, 1918, not July 1, as was indicated by earlier reports.

If 10,000 Liberty equipped airplanes had been shipped across when the earlier criticisms of the program were made there would have been no facilities for handling them.

In a recent convoy all of the transports, twelve in number, carried Liberty engines and American made airplanes as a part of their cargoes.

The loss of the first five Liberty airplanes flown from the American lines was due to lack of suitable landing ground and the planes landed by mistake within the German lines.

The Liberty engine is proclaimed the best that is made for flying purposes, and airplanes equipped with it have attained a speed of 135 m.p.h.

This statement and other interesting explanations of the airplane situation in France were made by Senator Thompson before the Senate recently, following the Senator's return from a trip through England and France.

## Plane Carries Twenty-one Passengers

He described one of the large Handley-Page bombing planes, type O-400, as capable of carrying 20 passengers besides the pilot and 2000 lb. of bombs in addition to the machine gun equipment, fore and aft as well as in the center. Following is that part of the Senator's address relating to aircraft:

"I also visited various training and flying schools, both in France and England, including the largest flying school in the world at Issoudun, which has about 5000 enlisted men and about 800 officers and a total student membership of about 2000, all of whom are American young men, including a number of Kansas boys. Here they are given about 6 weeks' final training and taught to use all kinds of planes, including the three different types required for all flying squadrons, namely, the fighting or scouting plane, called in the United States service the pursuit plane; the battle, observation, or reconnaissance plane, and the bombing plane. The fliers are divided into three classes and are permitted to choose service with the character of plane they are best able to handle.

"I also inspected the largest aviation assembling plant in the world at Romorantin. Here is where most of the Liberty motors are being installed in the De Haviland 4 and De Haviland 9 planes, commonly referred to as the D.H.4 and the D.H.9. Some criticism on this side of the Atlantic has been made for the delay in the delivery of this character of planes, the erroneous statement being

made on the floor of the Senate as late as last July that there was only one Liberty motor battleplane in Europe. The truth is, delivery of these planes was not expected earlier than July, while, as a matter of fact, the first Liberty motor plane arrived, was set up complete and christened on May 18, 1918, and they have been arriving over there at the rate of five to ten per day ever since.

"Every transport on our way over to France—twelve in number—carried Liberty motors and planes. Complaint was also made because we did not have as many as 10,000 or 20,000 planes over there, when, as a matter of fact, if they had been there they could not have been used, because there was not sufficient hangars or aerodromes to take care of them, or ample flying stations or fields from which to fly and land; and neither was there a sufficient number of fliers or competent men in the aviation service to properly take care of the planes or a sufficient supply of gasoline or lubricating oil.

"The first five Liberty planes had the misfortune to land within the German lines by mistake, so the importance of having suitable grounds on which to land, and to know where to land, can readily be seen.

"It requires about fifty experienced men and three extra planes behind the lines to keep one man flying. While, of course, there was some delay in the development of this wonderful Liberty motor, which is not to be wondered at, but having produced the best motor in existence rather than adopting some inferior motor, it has certainly been worth whatever loss has been caused by the delay and will prove a greater benefit in the long run. The fact is, that the Allies predominate in the air as they do in manpower and in artillery. It is, indeed, gratifying to know, however, that the delay has ended and that planes are now arriving at the distributing points in France about as rapidly as they can be taken care of.

## De Haviland Is Good All-Purpose Plane

"I enjoyed a flight over France in one of the completed and thoroughly equipped Liberty D.H.4. planes. This plane is regarded by experts to be the best all-purpose plane in existence, one that can be used fairly successfully for all three purposes required in a flight, to wit, battling, observation, and bombing. They are each modernly equipped, carrying a pilot who is armed with a Marlin machine gun capable of shooting 600 shots per minute, and the propeller in front of him so synchronized with the gun as to permit the pilot to fire right between the blades without hitting them, and also carrying an observer armed with a Lewis machine gun, which has a greater shooting ability, because it has an independent train and can be pointed in any direction.

"The D.H.4 Liberty plane weighs about 3800 lb., equipped with pilot and observer, and carries 500 lb. of bombs, equally divided, hanging from each wing, and so arranged that the operator may drop the bombs in 50-pound packages, or, if he prefers, can drop the whole 500 lb. at one time. Each plane is also equipped with wireless-telegraph outfit, besides other modern devices for navigation and communication.

"It was also my privilege to visit the Handley-Page plant in England, and on Sept. 1 to enjoy a flight over the city of London in one of the large Handley-Page bombing planes, the type commonly known as O-4000, which can carry 20 passengers besides the pilot, and 2000 lb. of bombs besides machine-gun equipment, fore and aft as well as in the center. The wings of this plane measure 100 ft. spread from tip to tip, and the body is 65 ft. in length, and the plane weighs without equipment 3½ tons and can carry in addition almost its own weight, so that it weighs when fully equipped about 6 tons and costs about \$30,000. It has two 350-hp. motors, both the Rolls-Royce and Liberty motors being used, placed on each side of the nose of the machine instead of directly in front, with platforms built so that the motor can be cranked or repaired in the air. It carries 300 gal. of gasoline and can travel about 800 miles without landing.

## Superairplane to Carry 50 Fighters

"While this may seem like a big story, yet this plant is now turning out another plane twice as large and with more than twice the capacity, carrying 50 passengers, over 2 tons of bombs, and will be able to fly from London to Berlin, bomb that city, and return home without leaving the air. I would not give these facts, except I know they are well known to the enemy by reason of the fact that the very first Handley-Page plane put into commission on trial by the British landed within the German lines by mistake, and Germany immediately began to duplicate it. This, however, was a good thing for Mr. Page, for after a long, hard struggle to get recognition from his own Government for the production of this wonderful machine, as soon as it was adopted by Germany, it was immediately approved by the British, and now they cannot be manufactured fast enough. I had the good fortune to witness several airplane battles at Chateau-Thierry, Verdun, Belgium and along the English front near Amiens.

"I also visited various flying schools in England, principally at Chattis Hill, near Winchester, where I took another airplane flight and flew over to a large flying school at Lecombe Corner, some distance away, and back again. We have 72 different flying schools in England in connection with the English aviators, both American and English fliers being trained and fitted for service, and from which place the fliers are sent to the front in France as they become proficient.

"Special attention is given to the training of all young men for the service they are to perform before they are placed in danger. Every possible precaution is taken to protect them by our Government. There are six rest camps in England where those who disembark on English shores rest up before going to France to enter the training camps there. I learned of at least 14 different kinds of schools in France, as follows: Artillery, airplane and photography, observers, transportation facilities, blacksmithing and repairs, gas schools, machine-gun and automatic rifle, Signal Corps, French mortar, pigeon schools (training the handling of, and caring for, pigeons for messenger service), engineers, camouflage, Army school of the line, and General Staff College."

## Stock of Petroleum Decreases

Oil on Hand During First Half of Year 12 Per Cent Less Than During Last Year

WASHINGTON, Sept. 30—In the first half of 1918, 12,397,660 barrels of crude petroleum were marketed, as compared with 12,114,179 barrels marketed in the same period of 1917. The consumption for the first 6 months of 1918 total 12,669,181 barrels as compared with 11,619,674 for the same period in 1917. The stocks at the end of each of the first 6 months of 1918 show a decrease of approximately 12 per cent as compared with the stocks at the end of each similar month in 1917. Herewith are the tables as prepared by the Department of Interior.

WASHINGTON, Sept. 30—Oil refineries throughout the country have been requested to increase kerosene production to the fullest extent to forestall a possible shortage during the coming winter by M. L. Requa, Director of the Oil Division of the United States Fuel Administration.

Kerosene consumption is increasing,

stated Mr. Requa, and unless immediate steps are taken to increase the supply we will face a shortage this winter, more acute than any experienced with other petroleum products. Following is the letter in full, which was sent to all refineries by Mr. Requa:

I am convinced it is absolutely necessary that the kerosene production of the country be materially increased. Statistically, kerosene is in a more unsatisfactory position than gasoline or fuel oil. We have not heretofore felt the acuteness of this situation because of the summer season through which we have just passed. Now, however, we are approaching the season of maximum kerosene consumption and unless steps are taken immediately to provide increased supply we shall undoubtedly this winter face a shortage much more acute than we have as yet experienced in any of the petroleum products.

The statistics now in the hands of your Sub-Committee show clearly the decrease in the percentage output of kerosene by practically all refineries. The situation as a whole shows decrease in barrels produced and a very large increase in domestic consumption which fortunately has been offset by a decrease in exports due to lack of tonnage for overseas movement. This export movement is now increasing, and the winter will soon be upon us. I request, therefore, that you communicate with each refinery, forwarding them a copy of this letter, and urge upon them the absolute necessity of increasing their kerosene production to the fullest extent possible, at least to a percentage amount equal to that of last year.

## Gasoline from Gas Gains 111%

Output During 1917 Is 114,391,415 Gallons Ahead of Production in Year 1916

WASHINGTON, Sept. 30—The natural-gas gasoline industry in the United States produced 217,884,104 gals. of gasoline by means of compression, absorption, vacuum pumps and the drip system, a gain of 114,391,415 gals. or 111 per cent over the output in 1916. Of this quantity 77.5 per cent was covered by compression and by vacuum pumps, and the remaining 22.5 per cent by absorption and by salvage from the gas mains. The combined production of gasoline obtained by compression and vacuum pumps was 99 per cent greater than that obtained in 1916, and the production secured by absorption and drips was 110 per cent greater.

Market Value Gains 180 Per Cent

Slightly more than 300,000,000 gals. of commercial gasoline was secured from the total output in 1917. The average price paid in 1917 for the raw production at the sources of production was 18.45 cents per gallon and the market value of the

Includes about 2,000,000 barrels of refinery products included in stock totals prior to May. Statistics for the California field in 1918 were furnished by the Standard Oil Co. (California), the Independent Oil Producers Agency, and the Pacific Coast Petroleum War Service Committee. Statistics of crude oil marketed in 1918 include runs of 4,643,000 barrels net from producers field tanks.

entire output was \$40,188,956, a gain of 180 per cent in gross market value as compared with 1916.

It is estimated that 429,000,000,000 cu. ft. of natural gas was used to produce the gasoline, and the average recovery of gasoline per 1000 cu. ft. was about one-half gallon. The tables include the essential statistics of the natural-gas gasoline industry in the United States in 1917.

### Urge Gasoline Cards

WASHINGTON, Sept. 27 — Recommendation for a card system to be used for gasoline distribution "during the gasoline shortage" was made in Congress yesterday by Congressman Focht. The recommendation was the result of a letter from a constituent, a farmer, who pointed out what he considered the injustice of the Sunday gasolineless program. The farmer, he said, working in his field on week days, witnessing the cars driving by, able only to use his on Sundays, considers it an injustice to be prohibited from the use of passenger cars on Sunday while others with more leisure might use theirs during the week.

### U. S. Produces Most Petroleum

WASHINGTON, Sept. 30—Five hundred million six hundred fifty-one thousand eighty-six barrels of petroleum were produced in 1917, according to a statement by the United States Geological Survey, Department of Interior. Of this amount 66.98 per cent was produced by the United States. This is 5 times greater than the amount produced by Russia, which ranks second.

The production for the 40 years extending from 1857 to 1917 total 6,983,567,246 barrels. During this period the United States led in production with an output of 60.89 per cent of the total amount.

### August Oil Exports 9,553,294 Gal.

WASHINGTON, Sept. 26 — Crude mineral oil exports for August were 9,553,294 gals. valued at \$560,642, as compared with 12,192,207 gals. valued at \$408,280 for August, 1917. Exports of gasoline, naphtha, etc., amounted to 56,944,192 gals. valued at \$13,677,715 for August, 1918, as compared with 30,593,418 gals. valued at \$7,275,604 for August, 1917, showing an increase of 85 per cent. Herewith is the summary of oil exports.

### World's Production of Crude Petroleum in 1917, and Since 1857, by Countries

Country	PRODUCTION, 1917			TOTAL PRODUCTION, 1857-1917		
	Barrels of 42 Gallons	Metric Tons	Per Cent of Total	Barrels of 42 Gallons	Metric Tons	Per Cent of Total
United States	335,315,801	44,708,747	66.98	4,252,644,003	567,019,201	60.89
Russia	669,000,000	9,418,509	13.78	1,832,583,017	242,336,182	26.24
Mexico	55,292,770	8,264,266	11.04	222,082,472	33,166,241	3.18
Dutch East Indies	12,928,956	1,778,495	2.58	175,103,267	23,628,200	2.51
India	68,500,000	1,133,333	1.70	98,583,522	13,144,469	2.41
Galicia	5,965,447	829,629	1.19	148,459,653	20,646,663	2.13
Japan and Formosa	2,898,654	386,487	.58	36,065,454	4,808,727	.52
Rumania	2,681,870	357,000	.54	142,992,465	19,283,174	2.05

dDrips only.

## Mail Applications for Preference

### N.A.C.C. Sending Out Forms for Passenger Car and Truck Makers to File with W.I.B.

NEW YORK, Oct. 1—The National Automobile Chamber of Commerce is this week sending to passenger car and motor truck manufacturers Application Forms for Places on the Preference List. This is known as "P. L. Form No. 1" and, it is explained, should be filled out and sent at once to the Priorities Division of the War Industries Board, Washington. If the form is approved, the manufacturer is placed on the preference list for fuel, labor, materials and transportation in view of shortages.

In filing the form, makers of trucks are instructed to state that it is in accordance with Circular No. 11 of the War Industries Board and Circular No. 177 of the N. A. C. C., relating to priority for materials for trucks under pledges that such vehicles are to be sold for essential purposes. Passenger car makers, in filing the form should state that it is in accordance with their agreement with the War Industries Board as made plain in that Board's letter to the N. A. C. C. relating to preferential treatment for materials for passenger cars to

be produced during the last half of 1918. The forms are reproduced herewith.

### Marine Engine War Service Committee Formed

WASHINGTON, Sept. 28—Members of the Marine internal combustion engine and accessory industry met here yesterday at the direction of the Chamber of Commerce of the United States and elected a War Service Committee to represent the industry as a point of contact with the Government. The names of the committee are not yet made public and will not be until each member elected signifies his acceptance, following which the names will be certified by the Chamber of Commerce and announced.

### Coal Production Drops Slightly

WASHINGTON, Oct. 1—Bituminous coal production for the week ending Sept. 21 was 12,650,000 tons. This is 4 per cent below the production of the week of Sept. 14, but exceeds the production of the corresponding week of 1917 by 19.4 per cent or 2,060,000 tons. The anthracite coal output for the week ending Sept. 21 was 1,847,000 tons, a decrease of 11.5 per cent as compared with the preceding week and a decrease of 2.1 per cent against the corresponding week of 1917. The loss in anthracite production was due to a strike.

## Government Control of Platinum

### Licenses Required for Sales, Production, Use and Grading —Supply Far Short

WASHINGTON, Sept. 27—Regulations have been completed for the licensing of the sale, use, production and trading in platinum, iridium, palladium, sulphuric acid or other mineral products containing these metals. Licenses will also be required for the use of these metals for manufacturing purposes. The regulations limiting the sale, possession and use of these metals have been drawn up by the Bureau of Mines to be enacted by the War Industries Board, in accord with a Congressional act.

It is unlawful under the regulations for any person without a license to purchase, sell or trade in these metals or to possess 1 oz. troy or more of unmanufactured platinum, iridium, palladium or the compounds for more than 90 days. Licenses are required to purchase, sell or trade in these metals, unmanufactured, except that sales can be made without a license to an authorized agent of the United States or to a licensee who has been given permission to make the purchase. Licenses are required also for:

Producing these metals by mining.

P. L. Form No. 1

**APPLICATION  
FOR PLACE ON  
PREFERENCE LIST**

TO THE PRIORITIES BOARD,  
OF WAR INDUSTRIES BOARD,  
Washington, D. C.

The undersigned hereby makes request to be placed on Preference List of industries and plants for the reasons stated below

**DEFINITIONS OF TERMS.**

- The term "the Allies" shall be taken to mean the nations associated with the United States in the war in which it is now engaged.
- The term "Government" includes the United States Government and the Allies.
- The term "direct Government orders" signifies any order or contract placed by the War Department or the Navy Department of the United States, or the U. S. Shipping Board Emergency Fleet Corporation, or by the Allies.
- The term "indirect Government orders" signifies materials, supplies, or equipment necessary in the manufacture of or in component parts of direct Government orders.
- Work of exceptional or national importance shall be taken to mean work which, while not primarily designed for the prosecution of the war, yet is of great public interest and essential to the national welfare, such as equipment and supplies for railroads and other public utilities, equipment and tools for mining of fuel and ores required in war work; agricultural implements, food accessories, repairs to existing industrial machinery, and other work of similar character.

**NOTE.**—If there is insufficient room to answer printed questions, use separate sheets) attached to completed questions, or table pages ten and four may be used.

1	Insert here name and address of applicant.	Name General office address
2	Location of particular plant for which preference is requested. Separate applications for each plant.	City or town Served by what railroad
3	Nature of product or products. If more than one, approximate per cent of each in total production.	
4	Principal uses which are made of your products, approximate per cent for each use.	
5	List here the machines, tools, and equipment necessary for the production of your products. (Limit entries to those which are essential to the production of your products.)	

Answer to Questions 6, 7, and 8 should represent only the percentage of output which is being applied to unfilled orders. Each percentage in connection with the answer to No. 9 should make sense.

Classification of work on hand.	Per cent.	Description, War Order number, etc.	Estimated time required for completion.
6	What per cent of applicant's total output is now devoted to direct Government orders?		
7	What per cent of applicant's total output is now devoted to indirect Government orders?		
8	What per cent of work is "of exceptional or national importance" as above defined?	State why work is of exceptional or national importance	
9	All other work (percentage).		
Total.		100%	
10	Close approximate monthly requirements of fuel for all purposes.	(a) Coal (tons). (b) Coke (tons). (c) Fuel oil (gallons). (d) Gas (cu. ft.).	11 Number of employees: (a) Men (b) Women 12 Paid on hand
13	Further information considered to be of importance in the consideration of this application.		

The undersigned, being first duly sworn, on oath says that the statements contained in the foregoing application are full, true, and correct.

Subscribed and sworn to before me this \_\_\_\_\_ day  
of \_\_\_\_\_, 1918.

Notary Public

in and for \_\_\_\_\_

By \_\_\_\_\_  
(Name of officer legally empowered to act for applicant.)

Forms which manufacturers of passenger cars and commercial vehicles must fill out and file with the War Industries Board to have themselves placed on the Preference List for fuel, materials and transportation

Producing sulphuric acid or other chemical products where platinum, iridium or palladium is used in the production.

Importing or exporting these metals.

Producing platinum, iridium or palladium either as a primary product or as a by-product by smelting or refining.

Manufacturing electrical appliances or parts containing these metals.

Manufacturing scientific instruments containing them.

Manufacturing or producing any article or product not mentioned above, including chemical, dental, surgical or jewelry supplies containing these metals, where such business requires more than 1 oz. troy per month of platinum, iridium or palladium.

Platinum compounds are used for contact points in ignition systems for airplanes, trucks and all kinds of automotive apparatus as well as in telegraph and telephone instruments.

#### Present Demand and Supply

Representatives of the War Industries Board have set forth the sudden and great increases that the government authorities had found it necessary to make in connection with platinum, etc., requirements. In fact, the government's estimate of requirements was only 40,000 ounces in March and 69,000 in June. Their statement of stocks on hand, while large, is not reassuring should the war continue for years, and the Russian platinum mining be long suspended by internal revolution.

For the year 1913 the world's production of crude platinum has been given at about 313,000 ounces troy, while for 1917 only 83,000 ounces; thus at present there is obtained from all the mines only 26½ per cent of the pre-war output. In 1913 Russia was credited with 95 per cent of the total and in 1917 only 60 per cent.

#### Platinum Discovered in 1735

Iridium is associated with platinum and the supply of this metal is for the most part obtained from the platinum deposits of Russia. Platinum was discovered on Colombia, South America, in 1735. In 1810 it commanded only from 30 to 40 cents an ounce. It was found in Russia in 1819. In 1828 it had a value of about \$7 an ounce. The fluctuation in values of platinum and iridium from 1901 to 1914 is most noticeable, the price per troy ounce of platinum varying from \$14 to \$36. Since 1914 platinum and all allied metals have varied in price as follows: For 1914, platinum \$45, iridium \$65, and palladium \$44; 1915, platinum \$55, iridium \$83, and palladium \$67; 1917 platinum \$103, iridium \$150, and palladium \$110; 1918, platinum \$105, iridium \$175, and palladium \$185, the Government fixed prices.

Next to Russia, Colombia produces the largest amount of platinum and presents the most promise of larger future outputs under stimulus of higher prices. Platinum in this country is found in many places but in small quantity, being less than 1 per cent of the world's production, but with the present high price its discovery and production in this country may be somewhat increased.

## 14 Solid Tire Sizes Now Standard

### War Board Reduces List from Over 100—Mostly Affects 1 to 2-Ton Trucks

WASHINGTON, Sept. 30—Sizes of solid tires will be reduced from a range of more than 100 types and sizes to 14 types and sizes within the next 2 years. An immediate reduction to 40 sizes has been ordered and this will be lowered to 36 on Nov. 1. Following that date there will be a gradual elimination of other types and sizes at specific periods until the minimum number is attained. The use of caustic soda in tire manufacture is to be discontinued at once.

The effect of the reduction within the next two years of solid tire sizes from more than one hundred to fourteen will not by any means be serious. Approximately one-third the total number of truck manufacturers will be affected, but only in so far as their smaller models are concerned.

Analysis of the sizes to be eliminated and those to be continued reveals that 114 separate models of trucks produced by various manufacturers will be affected. Of these models 28 are 1-ton, 36 are 1½-ton and 27 are 2-ton, which is a total of 91, leaving only 23 other models of capacities varying from ¾ to 6 tons which are affected. Practically all manufacturers producing vehicles larger than 2 tons already have adopted tire sizes which fit in with the standardized sizes to be adopted.

These plans are the result of a series of conferences between representatives of the industry and the War Industries Board, held to standardize the sizes and types of solid tires, to reduce the amount of labor, material and capital used. Following is the standardized program:

**Class A**, which is the range of standardized sizes and types which will be continued, includes hard base pressed-on and all removable types of tires of the following sizes:

32x3	36x4	40x5
32x3½	36x5	40x6
32x4	36x6	40x10
	36x7	40x12
	36x7	40x12
	36x8	40x14
	36x10	

**Class B**, which is the range which will be discontinued no later than Nov. 1, 1920, includes hard base pressed-on and all removable types of tires of the following sizes:

30x3½	34x3	36x3½	40x7
	34x3½		
	34x4		
	34x5		38x5

**Class C**, which is the range to be discontinued in manufacture no later than Nov. 1, 1919, includes hard base pressed-on and all removable types of tires:

32x3½	34x6	36x8	38x4
			38x5
			38x6
			38x6

**Class D**, the range which will be discontinued on Nov. 1, 1918, includes hard

base pressed-on and all removable types of tires:

34x3½	42x5	38x4½
	42x6	

**Class E**, which will be discontinued at once, includes all types and sizes of solid tires not specified in the above classes.

#### Continue Tire Production at 50 Per Cent

NEW YORK, Oct. 1—Production of pneumatic tires during October, November and December is to be continued at the same rate as during August and September, namely 50 per cent of normal production. During this period tire manufacturers will be allotted only one-third of their normal quantity of rubber. This means that they must use up all surplus stocks. Those who are close to the situation state that such surplus stocks are ample to permit this fifty per cent production of tires. The War Industries Board, which has made these rulings, hereafter will consider the rubber industry as a controlled industry. Restriction of pneumatic tire production applies only to casings and tubes smaller than 6 in. section. There will be no restriction of 6 in. or larger tires. No restriction will at present be placed on the production of solid tires.

#### G. M. C. Buys Jim Dandy Cultivator

CHICAGO, Sept. 30—The General Motors Corp. has purchased the Jim Dandy Motor Cultivator, hitherto made by the S. K. & S. Co., El Paso, Ill., and manufacturing facilities will be moved to Janesville, Wis. For the coming season it is probable the production will be from the factory of the Janesville Machine Co., but will be made a part of the production of the G. M. C. tractor factory at Janesville, as soon as the latter is completed. The Jim Dandy motor cultivator is of distinct type since it is belt driven. In one row model it can be driven with reins and is easier managed and handled than is a team of horses. The 2-row model is constructed so that the cultivator beams may be dropped and a draw bar substituted for the hauling of any of the lighter utensils on the farm.

#### No Children on War Work

WASHINGTON, Sept. 30—Children under 14 years of age cannot be employed on war work. Children between 14 and 16 years of age cannot be employed more than 8 hours a day nor before 6 a. m. or after 7 p. m., and no more than 6 days per week on war work. These regulations were announced to-day by the War Labor Policies Board. The board states further that the prohibition of employment of children below certain ages does not imply that their employment above these ages is favored. It merely states these regulations because of the great demands that children be included in the industrial war effort for war. It points out that 14 or 16 years of age workers are certain to be workers in their lat-

## Marines Have U. S. Made Outfit

### First Aviation Unit to Go Overseas with American Built Equipment

WASHINGTON, Sept. 28—The first aviation unit organized in this country and sent abroad using American-made material was the First Marine Aero-nautic company, equipped for water flying only, which is stationed abroad at a naval base. This information is made public in an announcement of the Marine Corps Aviation.

In addition to maintaining a flying field at Miami, Florida, where actual flying training is given, the aviation Section of the Marine Corps gives candidates instruction in ground work at the Massachusetts Institute of Technology, Boston, and has two schools for instruction in aviation mechanics.

The flying course at Miami covers 75 days, and includes preliminary, acrobatic and formation flying combined with instruction in bombing, gunnery and reconnaissance. There are now 289 students at the Massachusetts Institute of Technology. When marines are assigned to this school they are enrolled as Gunnery Sergeants for the duration of the course and receive the pay allotted to this rank.

#### Chance For Promotion

Those who show themselves as promising material are made officers after completing their training as flyers. The ground course lasts 10 weeks and 80 men are graduated each month. One hundred men kept in reserve at all times insures against a break in supply of men to the school. If a man fails to be graduated he has the option of being transferred to training for regular duty in the Marine Corps or being discharged.

Of the two schools for mechanics, the larger is maintained at the Naval School for Mechanics, Marine Corps Section, Great Lakes Training Station, Chicago, Ill. Here Marines are trained as mechanics, riggers and armorers. At present there are 120 enlisted men taking the course at Great Lakes, and 60 men are sent each month from the Marine Corps. The total number of men allotted to the Marine Corps at one time is 360.

The second school for aviation mechanics is located at the Naval School, Marine Corps Section, San Diego, California. The training is the same as given at the Great Lakes School. Ninety-three enlisted Marines are taking the course at the present time. The capacity is 120.

#### Hanch Increases Production for Two

WASHINGTON, Oct. 1—Some idea of the relief some truck manufacturers may expect from the action of the War Industries Board restricting production during the last half of this year to one-third of

the number of vehicles produced during the last 18 months is given by decisions of Charles C. Hanch, chief of the Automotive Products Section, early this week. It is understood that two manufacturers already have had their apportionments increased, both by practically 50 per cent. Hanch is given latitude by the War Industries Board to increase or decrease apportionments. It is understood that he will decide individual cases and that a number of truck manufacturers at present have appeals pending.

#### The Pfalz Single-Seater Fighter

(Continued from page 593)

the illustrations. As in all German machines, ailerons are fitted to the top plane only, and their crank levers are horizontal, working in slots in the plane. The aileron hinges on a false spar. The crank levers are built up of two halves of sheet steel, pressed to form in section one-half of an ellipse. The two halves are then welded together along the edges. The control cables are secured to the crank lever by the same ball-and-socket attachment as that employed for the rudder and elevator controls already described. The cables pass from the lever, around pulleys in the bottom wing, and through tubes to the controls. These tubes appear to be made of some sort of paper or cardboard, although whether made by wrapping the paper spirally or rolled up straight to form a tube we have not been able to ascertain.

Reference has already been made to the fact that the radiator of the Pfalz is mounted in the top plane. The cooling may be varied by an adjustable shutter which has a handle projecting back so as to be within the reach of the pilot. The rod carrying the handle has a series of notches cut in it so as to form suitable stops for the shutter in any desired position. The details of the locking device are included in the sketch of this part.

The armament of the Pfalz consists of two synchronized machine guns of the Spandau type. Two transverse tubes form the supports for the gun mounting, which appears very light, being made of light gage steel suitably reinforced by webs in places. The rear attachment of the gun provides for vertical adjustment, while the front attachment enables a slight lateral alignment of the gun after the mounting has been bolted into place on the cross tubes. A peculiarity of the gun placing on this particular Pfalz is that the guns are entirely inclosed under the top covering of the body, with only the muzzle projecting. On a later specimen of the Pfalz fighter the more usual placing of the guns above the body has been employed, whether because inclosing the guns was found unsatisfactory or not we are not in a position to say. Probably the inclosed guns were found to have a tendency to overheat.

In the Pfalz under review no attempt appears to have been made to camouflage the machine, which is painted with aluminum paint all over its body and wings. The rudder tail plane and elevator are painted a dark yellow.

## Egypt Fair Market After War

### Few Cars Entering Now—Introduction of Trucks and Tractors Needs Education

CAIRO, EGYPT, June 30—Very few automobiles are now being imported into Egypt for private use owing to war conditions and the difficulty of shipping facilities from American ports. This applies to cars for use by civilians. The British army uses a very large number of cars of all types, all of which are purchased through the war office in London.

There should be a fair demand for automobiles in Egypt after the close of the war. The possible buyers are found in the European population resident here and also among the wealthier Egyptian natives. Automobiles in Egypt largely are used in the three centers—Cairo, Alexandria and Port Said. There are a few in the smaller Egyptian cities, but the roads throughout Egypt are not yet sufficient in number or of such character as to encourage automobiling generally throughout the country. Roads are improving each year.

Egypt should be a good market for gasoline farm tractors, and after the war those American firms having energetic Egyptian representation will undoubtedly meet with success and sell a fair number of these tractors.

Motor trucks are not largely used in Egypt, although a few of the larger stores in Cairo have motor delivery wagons. The heavy truck or camion is practically unknown except for army uses.

The reasons for the few trucks in use is partly found in the fact that Egypt has not sold many horses because of the war demand, although a large number of camions and donkeys have been purchased by the British army for the Palestine campaign.

This has not affected the question of local transportation to the point where business houses will look to motor trucks or even to farm tractors to make up for the loss in animal power because of the war. Both agriculture and transportation have been carried on in a crude way in Egypt and it is going to call for an educational campaign before these conditions will change.

#### Ohio Labor Shortage Acute

TOLEDO, Sept. 20—According to reports from twenty-one local United States employment offices throughout Ohio the state's labor shortage continues to be acute. The records show that approximately 10,000 jobs were filled during the week ended Sept. 14. There were 17,074 requests for help. Applicants totaled 14,352. Out of the 4182 requests for female help 2488 took positions. There were 227 applications for farm work and 132 took jobs. Requests for farm work numbered 229.

## Production Uncertainty Bothers Truck Makers

NEW YORK, Oct. 3—It is expected that as a result of the meeting of the Motor Truck Committee of the National Automobile Chamber of Commerce which is to be held this afternoon, the situation with regard to production will be materially clarified. Manufacturers are at odds and end following the recent ruling of the War Industries Board curtailing production during the last half of the year to one-third of the output during the past 18 months and this is one question which is to be threshed out.

At the time the Highways Transport Committee was getting into its stride, no hint of curtailment had appeared and it was with the probability of full production that this committee's plans were developed. Now, however, that a curtailment appears imminent, it may be that considerable revision of such plans will be necessary. It is understood, in fact, that certain plans now under consideration are entirely held up and will not be acted upon until some assurance regarding future production is forthcoming.

That there may be some relief is apparent from the action of Charles C. Hanch, chairman of the Automotive Products Division of the War Industries Board, who already has been instrumental in having the allotments of two manufacturers increased by practically 50 per cent.

The directors of the N. A. C. C. held their regular monthly meeting yesterday. This is to be followed to-day by the regular meeting of members, after which will come the meeting of the truck committee. At the director's meeting, the consensus of opinion was that members of the association will not oppose any taxation which in the opinion of government is necessary.

### Detroit Subscribes 25 Per Cent Quota

DETROIT, Oct. 2—Over 25 per cent of Detroit's \$74,000,000 quota was subscribed by the fourth day of the campaign. The total now stands over \$19,000,000. The fourth day brought nearly \$5,000,000. Among the subscribers were the following:

Packard	\$1,000,000
Hudson	700,000
Fisher Body Co.	500,000
Cadillac Motor Car Co.	450,000
Maxwell-Chalmers	300,000
Studebaker Corp.	250,000
Detroit Copper & Brass	250,000
Timken-Detroit Axle Co.	225,000
Continental Motors Corp.	200,000
Hudson (employees)	178,000
Detroit Iron & Steel Co.	100,000
Nich. Smelting & Refining	100,000
Paige	100,000
Detroit Lubricator	119,600
Michigan Steel Castings	111,000
Morgan & Wright	100,000
Michigan Lubricator (employees)	52,000
Michigan Malleable Iron (employees)	50,000
Northway Motor	50,000
Buhl Stamping	50,000
Jeffery-DeWitt Co.	40,000
Michigan Lubricator	27,000
Anderson Electric Car Co.	25,000
Buhl Malleable Co.	25,000
Sherwood Brass (employees)	25,400
Total	\$5,078,000

Toledo corporations and individual members subscribed a total of \$3,635,000 the first day of the loan or nearly one-fifth of the entire quota of the city and county.

Another view of one of the British Whippet tanks which are doing such effective work on the Western front. These are being operated in conjunction with the cavalry and have been quite successful in the Allied drive at Picardy. The civilian in the picture is the Prime Minister of Newfoundland

Willys-Overland	\$1,500,000
Auto-Lite Electric Co.	300,000
Champion Spark Plug Co.	\$150,000

Flint's factory men have already oversubscribed their quota of \$1,111,725, having pledged \$1,254,270 or an oversubscription of \$150,000 of the total subscription to date. The Buick shops which head the list show nearly half of the subscriptions with a total of over \$664,000.

Chevrolet Motor Co.	\$238,300
Champion Ignition Co.	109,100
Port Motor Co.	52,000
Flint Varnish & Color Works	25,000
Imperial Wheel Co.	10,200
Marvel Carburetor Co.	16,900
Walker Weiss Axle Co.	17,300
Weston Mott Co.	146,000
Grand Rapids Brass Co.	25,000
Haskelite Co.	20,000
Hayes Tonia Co.	50,000
Keeler Brass Co.	75,000
National Brass Co.	10,000

### Regulations Governing Tractor Production

WASHINGTON, Oct. 3—Under government control curtailing the use of steel and iron in the manufacture of farm tractors and farm equipment which was announced in AUTOMOTIVE INDUSTRIES last week, regulations issued to-day provide that tractor manufacturers who produced and sold 50 or more tractors Oct. 1, 1917 to Sept. 30, 1918, may not exceed 75 per cent of their consumption of iron and steel during that period in the year October, 1918, to Sept. 30, 1919. Tractor makers who produced and had in field operation 10 tractors and not more than 50 tractors during the last year, will not be allowed to produce over 50 tractors during the coming 12 months. Tractor manufacturers who produced less than 10 tractors in the last 12 months cannot produce more than 10 tractors during the year Oct. 1, 1918 to Sept. 30, 1918. Manufacturers of other farm equipment or machinery similar to farm tractors will also have to follow these regulations.

Signed pledges will be demanded from manufacturers by the War Industries

Board to use materials on hand or that come into their possession, solely for the manufacture of tractors, farm equipment and parts, to reduce the tonnage of iron and steel as provided by the regulations, to produce only the most essential farm equipment and parts and to distribute the products only for essential users which comply with the curtailment regulations of the War Industries Board providing for economies and substitution.

The tractor and farm equipment industries consumed 2,000,000 tons of iron and steel in the last year and it is expected that 500,000 tons will be saved for the direct war program by the curtailment.

Judge Parker, Priorities Commissioner, in a statement issued with the regulation acknowledged "that the farm tractor and farm implement industry is not only an essential but an actual indirect war industry." He pointed out the urgent need for steel and iron for direct war needs at this time, however, and makes this the reason for the curtailment.

### Wilson Made Curtiss Vice-President

BUFFALO, Oct. 2—At the monthly meeting of the board of directors of the Curtiss Aeroplane & Motor Corp. Charles Wilson was elected a director and vice-president in charge of production. Mr. Wilson is president and general manager of the Wilson Foundry & Machine Co., Pontiac.

### Ford's Eagle I In Test Runs

DETROIT, Oct. 1—Henry Ford's first sub-chaser—Eagle I—which was launched July 11, has been fitted up and is now making runs up and down the Detroit River in tests. Since the date of the launching of this boat six other Eagles have been put into the water. There are always twenty-one Eagles in the course of construction.

## Many Detroit Plants Enlarge

### Great Increase in War Work Necessitates Expansion—Building Permits Increase

DETROIT, Sept. 30—Due to the steady increase in the volume of war work in Detroit and surrounding territory many automobile and allied concerns find it necessary to erect new buildings and additions to increase their facilities for supplying the growing war requirements. An unusually large number of building permits for factory buildings and additions have been issued during the past few weeks.

The Packard Motor Car Co. is planning a one-story oil reclaiming station to be erected at the plant on East Grand Boulevard and the Michigan Central Railroad.

Dodge Brothers are contemplating a \$300,000 addition to the new building which was recently erected on Lynch Road to accommodate war work.

The Hudson Motor Car Co. has plans on foot for an additional plant building, 60 x 450, to cost in the neighborhood of \$60,000. It is reported that the building will be used for shell manufacture.

The Paige-Detroit Motor Car Co. will erect a one-story generator house building at the plant located on McKinstry Avenue.

The Swedish Crucible Steel Co. is building a one-story addition to its factory at Butler Avenue and the Grand Trunk Railroad.

The Parish Mfg. Co., manufacturer of automobile frames, will erect a two-story addition to its factory on Mt. Elliott Avenue, between Harper and Milwaukee Avenues.

The Detroit Copper & Brass Rolling Mills, which is practically on 100 per cent war work, has under construction the erection of a \$400,000 addition to its

factory at 1223-9 West Jefferson Avenue.

The Detroit Auto Piston Co. will erect a one and a half story factory addition, 60 by 104.

J. E. Bolles Iron Works is planning a one-story building to be erected at the plant located at Milwaukee Avenue and Grand Trunk Railroad.

The Continental Motors Corp. is making plans for a large power house to be erected at the Muskegon plant.

### Ball Bearings on Preferred List

WASHINGTON, Sept. 30—The manufacture of ball bearings and steel balls has been recognized as an essential industry by the War Industries Board. Any member of the industry whose plant is now or in the future shall be exclusively devoted to manufacturing products being or to be absorbed directly or entirely by the Government or in other uses of essential importance, may have his plant given a Class B-3 rating for steel and iron requirements. This rating is given upon the condition that the usual pledge of co-operation be signed and that the rules of the Priorities Division be followed. Manufacturers whose entire output does not go for Government use may file applications for places on the preference list and will be given preference according to the extent of their direct or indirect Government business.

### Caproni Climbs 13,500 Ft. in 46 Min.

NEW YORK, Oct. 1—In recent tests the Caproni bombing plane, fitted with three Liberty engines and carrying a load of 4650 lb., averaged 105 m.p.h. With this load it was able to climb to 6500 ft. in 16 min. It reached 10,000 ft. in 27 min. and 13,500 ft. in 46 min. The gasoline consumption approximated 30 gal. per engine per hour.

### Open Bids for 25,000 B Trucks

WASHINGTON, Oct. 1—Bids for 25,000 Class B 3-ton war trucks have been received by the Motors Division of the U. S. Army, and opened to-day.

## Latin America a Good Market

### Enormous Opportunities Offered Manufacturers of Automotive Products

NEW YORK, Sept. 30—A glance at the export statistics given in tabular form on this page is sufficient to indicate the enormous extent to which our trade in automotive products with Latin America increased during 1917 when compared with the figures for the previous year.

As compared with 1916, our 1917 passenger car exports increased 52 per cent in number and 76 per cent in value.

Our commercial car exports increased no less than 232 per cent in number and 210 per cent in value.

The value of parts exported increased 232 per cent, tires increased 107 per cent and the only decrease shown is that of gasoline, which is a fraction less than 5 per cent below 1916.

### 106 Per Cent Increase in Year

Considering the subject from another angle:

During the fiscal year ending June 30, 1916, the total value of cars, trucks, parts and tires exported to Latin-America by the United States was \$9,587,275. In 1917 the total had risen to \$19,796,917—an increase of over 106 per cent.

Total figures for the year ending June, 1918, are not yet available, but the exports of cars, trucks and parts to Latin-America from the Port of New York alone during the first seven months of the present year are valued at \$7,545,572, a record which is doubly remarkable when the serious shortage of shipping is taken into consideration. As a matter of fact, this seven months' record of shipments from New York is almost as great as the twelve months' totals on these items for 1916.

Exports of Passenger Cars, Commercial Cars, Parts, Tires and Gasoline from the United States to Latin American Countries for the Fiscal Years Ending June 30, 1916-1917

**Ranken Heads Purchasing Agents**

DETROIT, Sept. 28—The 1919 convention of the National Association of Purchasing Agents will be held in Philadelphia. Officers elected for the ensuing year are: President, D. D. Ranken, E. I. Du Pont De Nemours Powder Co., Wilmington; first vice-president, F. J. Solon, Owens Battle Machine Co., Toledo; second vice-president, J. A. Whaling, Solvay Process Co., Solvay, N. Y.; third vice-president, V. W. Bergenthal, Wagner Electric Mfg. Co., St. Louis; secretary, L. F. Boffey, New York; treasurer, John C. Dinsmore, University of Chicago. A membership drive is contemplated and a suggestion was offered that the organization apply for membership to the American Society for Testing Materials. Thirty-five members of the Michigan Institutional Buyers' Association have affiliated themselves with the Purchasing Agents.

John C. Toomey has been appointed district manager of L. A. Young Industries, Inc., Detroit.

L. A. Smith, assistant to T. J. Toner, director of sales and advertising of the Maxwell Motor Co., Inc., Detroit, has been placed in charge of Maxwell and Chalmers sales in the eastern territory, with headquarters in New York.

Charles B. Wilson, former general manager of the Wilson Foundry & Machine Co., Pontiac, has been appointed a director, with the rank of vice-president, of the Curtiss Aeroplane & Motors Corp., Buffalo. For the last 3 months he has been assistant in charge of production at the Curtiss plant.

E. L. Kreamer, formerly of the sales and advertising department of the Oakland Motor Co., Pontiac, has enlisted in the Motor Transport Division, and is now stationed at Washington, D. C.

E. D. Williams, formerly employment supervisor of the motor plant of the Oakland Motor Car Co., has associated himself with the Cleveland Tractor Co.

B. B. Holt, purchasing agent of the Harroun Motors Corp., Wayne, Mich., has tendered his resignation, effective Oct. 1, to become sales manager for the manufacturers' division of the Bradfield company. This division of the Bradfield company is at present furnishing material on war contracts in Michigan, Indiana and Ohio.

Jay E. Chilson has been appointed representative for Chicago for the L. H. Gilmer Co., Philadelphia.

H. F. Harris has been appointed general sales manager of the Republic Motor Truck Co., Alma, Mich.

Z. D. Barnes, non-ferrous metallurgist with the Westinghouse Air Brake Co. for the past few years, has joined the operat-

## Men of the Industry

*Changes in Personnel and  
Position*

ing department of the Aluminum Castings Co., and will make his headquarters in Cleveland.

**Paige Nearing 100 Per Cent War Basis**

DETROIT, Sept. 28—The Paige-Detroit company is fast approaching the 100 per cent war basis. In a few weeks all the resources of the company will be devoted exclusively to Government service. When the company has used its present supply of materials it will make no more passenger cars.

**Government Rents Ford Buildings**

WASHINGTON, Sept. 30—Seven buildings used by the Ford Motor Co. for distributing, assembling and service stations have been taken over by the Government. The buildings are located in St. Louis, Atlanta, Long Island City, Cambridge, Louisville, San Francisco and Philadelphia. The St. Louis building, which has 215,000 sq. ft. of floor space, will rent to the Government at 31½ cents per square foot, and will be used by the Depot Quartermaster. The Atlanta building, totaling 161,000 sq. ft., at a rental of 26 cents per square foot, will be used by the Reclamation Department of the Quartermaster Corps. The Long Island City building, 477,000 sq. ft., rental 31 cents per square foot, will be used by the Gas Defense Service. The Depot Quartermaster is using the Cambridge building, which has 160,000 sq. ft., at 32 cents per square foot. The Louisville plant of 83,000 sq. ft. is being used as a Medical Supply Depot at 24 cents per square foot. The Division of Military Aeronautics will take over the San Francisco building of 38,000 sq. ft. at 24 cents per square foot. The Ordnance Department and the Depot Quartermaster divide the Philadelphia Ford building for the monthly rental of \$1,420 per floor.

**Dort Prices Advance**

DETROIT, Oct. 1—The Dort Motor Car has increased the prices of its models as follows:

	New Price	Old Price
Touring and roadster...	\$985	\$925
Coupe and sedan.....	1415	1325
Sedanet .....	1150	1060

**May Stop Gasless Sundays**

WASHINGTON, Sept. 28—Gasolineless Sundays will continue indefinitely, but the ban may be lifted at any time, according to statements made yesterday by Dr. H. A. Garfield, United States Fuel Administrator.

**West Heads Wheel Makers**

CLEVELAND, Sept. 30—The next meeting of the Automotive Wheel Manufacturers' Association will be held here Oct. 10. At the last meeting of the association the following officers were elected: President, R. H. West, West Steel Casting Co.; vice-president, R. B. Flower, Standard Steel Casting Co.; treasurer, W. E. Burns, Michigan Malleable Iron Co.; secretary, George L. Lavery, West Steel Casting Co. Executive committee—H. A. Coffin, Detroit Pressed Steel Co.; R. D. Webster, Wire Wheel Corp. of America; George Walthers, Dayton Steel Foundry Co.

C. P. Kimball, president of C. P. Kimball & Co., Chicago, body and coach builders, has become president of the Great Lakes Tire Service, which handles the United States tires and tubes and specializes in tire service.

Lester E. Willson, formerly vice-president in charge of sales of the Briscoe Motor Corp., Jackson, has been appointed general sales manager of the Dauch Mfg. Co., Sandusky, Ohio. J. W. Wellington, formerly production manager of the New Castle, Ind., plant of the Maxwell Motor Co., has been made general manager of the Dauch company.

Charles H. Gresslee, formerly sales manager of the Selden Truck Sales Co., Cincinnati, has been appointed district sales manager of the All-American Truck Co., Chicago.

**Workers' Exemption Claims Filed**

DETROIT, Sept. 30—Through the filing of industrial exemption claims for its needed skilled men the Continental Motors Corp. has been successful in retaining 200 of its force, having been placed in a deferred class. The company has lost 1200 men, who have gone into military service. More than 6500 men are employed by the company, of whom 3000 are with the Muskegon plant. A careful record of the status of every man is kept by the company, which facilitates the filing of exemption claims when occasion arises.

**Railroads Want Highways Co-operation**

WASHINGTON, Sept. 30—The United States Railroad Administration has requested all firms or associations planning activities to assist the railroads to also consult with the regional directors of the Highways Transport Committee in their districts with a view to correlating the transportation work of the highways and railroads as much as possible. The Railroad Administration has directed all of its regional traffic assistants to co-operate as closely as possible in this work with the regional directors of the Highways Transport Committee. The highways regional directors have been instructed by the Highways Transport Committee to submit all plans for future organization or extension of operations to the committee for its examination and approval.

## Liberal Pension Plan of a Tool Manufacturing Company

AKRON, OHIO, Sept. 30—The Whitman & Barnes Mfg. Co. announces to its employees the establishment of a pensioning plan, which is most liberal in its provisions.

The plan goes into effect as of Sept. 1, and under it those eligible to apply for pensions are:

All employees who have been in the company's service continuously for 30 years or more; male employees who have reached the age of 60 years and female employees who have reached the age of 55 years, and who have been in the company's service continuously for 25 years; male employees 65 years of age and female employees 60 years of age who have been in the company's service continuously for 20 years; male employees 70 years of age and female employees 65 years of age who have been continuously in the company's service for 15 years.

The company bears all the expenses in connection with the administration of the pension system; no contributions from employees will be asked, and no assessments will be levied upon them.

Pensions will be paid monthly as follows: For each year of continuous service, 1 per cent of the average regular monthly pay during the 10 years preceding retirement. Bonuses and awards are not to be included in computing the average monthly pay. No pensions will be granted in amount more than \$100 per month, nor less than \$20 per month.

The company undertakes to continue the payment of the pensions for the life of the employee, and furthermore, should the employee be married and be survived by a widow, or widower as the case may be, the company will continue to pay the pension to the survivor so long as he or she remains unmarried and possesses no other income or means of support.

In case the employee receives compensation from the company or from any state, national or public fund, for disability incurred in the company's service, the pension granted will not be for a larger amount than will, when added to such other income, be equal to the amount of the pension computed upon the regular basis that such an employee would receive who did not receive other compensation.

Pensions may be refused or canceled in cases of criminal or gross misconduct, or assignment of pension, or in cases which the management deems advisable for cause.

The pensioner is given the privilege of engaging in any other line of work not prejudicial to the interest of the company.

In the cases of those who re-enter the service of the company after having been out of it for a while, the length of service considered in the matter of pension awards is figured from the time at which re-employment began. This provision of course does not hold in the case of such temporary absences as are incurred through illness or accident or temporary lay-off, because of a reduction in the working force.

Where the period during which an employee is out of the service of the company is less than one year, the employee is not considered as having been re-employed, but the time during which he was away from the company is deducted from his "length of

service" record in making pension calculations.

The entrance of employees into the Government service is covered by special provisions.

### Jurisdiction Over Flying Fields Altered

WASHINGTON, Sept. 28—The Air Service testing fields located at Dayton, Detroit, Buffalo and Elizabeth, N. J., have been transferred from the jurisdiction of the Bureau of Aircraft Production to the Division of Military Aeronautics.

The method of testing finished airplanes will undergo a complete change. Instead of flying each machine produced at least 1 hour before crating, as has been the practice, the fifteenth, twentieth or thirtieth plane, as may be decided, will be selected from the shop run, shipped directly to a testing squadron and given a trial, "flown to destruction." The other planes will be immediately crated and sent on the way.

As quickly as weaknesses develop in any of the machines tested, the fault found will be communicated both to the factory and overseas, and remedied before the planes take the air. It is expected that this plan combined with the present high efficiency of factory inspection of parts and assembly, will increase the speed with which airplanes reach the American Expeditionary Forces and at the same time insure the highest quality of service.

### Expansion of Royal Air Force

WASHINGTON, Oct. 1—The Royal Air Force of Great Britain, which numbered a total of 350 officers in June, 1915, contained 18,000 early this year. These figures have been announced by the British Aviation Mission in this country to emphasize the expansion of the air service since 1914.

In July, 1917, British pilots dropped 65 tons of bombs on German towns while in May, 1918, this increased to 686 tons and at the present time as much as 600 tons are dropped in a week. In July, 1916, 62 Hun planes were brought down and 36 British planes were missing, while in March, 1918, 574 German planes were brought down against 162 British planes missing. In July, 1916, 5000 aerial photographs were taken, while in March, 1918, 69,000 aerial photographs were brought in by the air service.

### Will Discuss Waterway Transportation

WASHINGTON, Oct. 1—New fields for important motor truck uses will be developed if the present plans for extending inland waterway transportation are developed. An important conference will be held here on Oct. 11 when delegates representing owners of boats on inland canals, members of chambers of commerce in cities located on or near the canals and others interested in waterway transportation will meet with the United States Railroad Administration and discuss the better distribution and more economic use of tonnage. Director-General McAdoo has been endeavoring for sometime to increase the usage of waterways and to bring about closer co-operation between them and the railroads.

## Women Workers Must Be Taught to Eat Properly

ST. LOUIS, Sept. 28—Perhaps the most interesting topics developed at the seventh annual convention of the National Safety Congress in session here last week were those in reference to the employment of women in new industries.

The matter of making women satisfied in their new fields came up in the wood-working section, and was echoed throughout the entire meeting.

F. D. Campau, secretary of the Furniture Manufacturers' Association of Grand Rapids, told of the means used there to interest women and keep them on the job. He said in explaining new conditions: "The greatest single stumbling block we found was that the women workers did not eat enough. Most of them were unused to work and came from homes where they could 'get a bite' at any time of the day. They came without sufficient breakfast and they refused to carry a large package of lunch and a lunch bucket was regarded as out of the question. The result was a headache in mid-afternoon.

"In overcoming this our factories tried serving milk and sandwiches for between-meals lunch. The sandwich caused trouble. The Jewish women refused the ham and were inclined to think we had offered them an insult. We changed to chicken and on Friday the Catholic women would not touch our offering. We compromised on a specially made, large, thick ginger cookie which is served with the milk. The headaches have disappeared and so has most of the discontent with factory work.

### Complete Dressing Rooms Needed

"Next came the problem of preparing suitable dressing rooms where even the most intimate garments could be exchanged. We have not found any women who are willing to go to and from home in working clothes. The lockers must have rooms for the skirts to hang full length, a place must be provided for large hats and there must be sufficient full length mirrors. Small mirrors are required in abundance.

"We have found that women can be interested in safety work more easily than men and more effectively. If a good social worker is not available, pick out some woman from the workers and instruct her in all of these things so that she may be a leader.

"We have found that care of injured or ill working women in a good hospital is a good investment. Often the women, as well as men, sent to a hospital get their first lesson in cleanliness, of living where there are sheets, proper night clothing, balanced diet and the lessons they learn there make them better employees. Especially is the effort to have the very best surgical treatment a lesson, for they quickly demand better from the family doctor for their family in case of need, and this better treatment which follows goes far to relieve their worries at home."

# AUTOMOTIVE MATERIALS MARKETS

## Materials Market Prices

<b>Acide:</b>	<b>Burlap:</b>
Muriatic, lb. .... .02-.03	8 oz., yd. .... 17½-17½

## AUTOMOBILE SHEET PRICES

(Based on No. 22 Gage. Other gages at usual differentials)

	Primes only Per 100 lbs.	Primes when seconds up to 15 per cent are taken Per 100 lbs.
Automobile body stock.....	\$5.95	\$5.85
Automobile body stock, deep stamping	6.20	6.10
Automobile body stock, extra deep stamping	6.45	6.35
Hood, flat fender, door and apron, or splash guard stock.....	6.05	5.95
Crown fender, cowl and radiator casing, deep stamping	6.30	6.20
Crown fender, cowl and radiator casing, extra deep stamping.....	6.55	6.45
Automobile Sheet Extras for Extreme Widths:		
Nos. 17 and 18 over 36 in. to 44 in., 10c. per 100 lb.		
Nos. 19 and 21 over 36 in. to 44 in., 30c. per 100 lb.		
Nos. 22 to 24 over 26 in. to 40 in., 40c. per 100 lb.		
Nos. 22 to 24 over 40 in. to 44 in., 80c. per 100 lb.		
Black Sheet Extras to Apply to Narrow Widths:		
Oiling, 10c. per 100 lb.		
Patent leveling, 25c. per 100 lb.		
Resquaring, 5 per cent of gage price after quality, finish and size extras have been added.		
Seconds 10 per cent less than the invoice Pittsburgh price for corresponding primes.		

## Don't Require Import Licenses

WASHINGTON, Sept. 28—Under new regulations many commodities can be imported into the United States from the United Kingdom, France or Italy or their European or Mediterranean African possessions without first securing an individual import license. The following commodities are those connected with the automotive industries specifically excluded from the terms of the new general license and will require the individual license:

Asbestos; castor oil, castor beans; chrome, chrome ore and chemicals extracted therefrom; cobalt, cobalt ore, and chemicals extracted therefrom; copper ore and copper concentrates; corundum; emery and emery ore; ferro-alloys; ferro-manganese; graphite or plumbago, and graphite crucibles; iridium; iron ore, lead, leather; all finished and all leather row stock; manganese, manganese ore; mica; molybdenum, molybdenum ore and chemicals extracted therefrom; palladium; platinum and manufactures of, pyrites; rubber, crude, scrap and reclaimed; balata, gutta, gutta serena, gutta percha, gutta serena, manufactures of rubber; tin in bars, blocks, pigs or grain or granulated, tin ore and tin concentrates or any chemical extracted

therefrom; titanium, titanium ore and chemicals extracted therefrom; tungsten, tungsten ore and chemicals extracted therefrom; vanadium, vanadium ore, and chemicals extracted therefrom.

## Requests Suspension of Racing

WASHINGTON, Sept. 30—Voluntary suspension, for the period of the war, of automobile, motorcycle and motor boat racing and speed contests has been asked by the United States Fuel Administration. The American Automobile Association, co-operating with the request, has assured the Fuel Administration that it will strictly observe it. Chairman Richard Kennerdell, of the Association Contest Board, stated that he has suspended operations and will issue no more sanctions for race meets or speed contests. Sanctions have been previously given for races to be held at Trenton, N. J.; Danbury, Conn.; Tucson and Phoenix, Ariz., and in Los Angeles, Cal., within the next 2 months, but it is expected by the Fuel Administration that the promoters of these contests will call off the events in order to meet the Administration's request.

## Sulphuric and Nitric Acid Prices Fixed

WASHINGTON, Sept. 27—The following maximum prices have been agreed upon for sulphuric and nitric acid as a result of conferences between the manufacturers of these and the Price Fixing Committee of the War Industries Board. The prices take effect Sept. 30, 1918, and expire Dec. 30, 1918:

Sulphuric Acid 60° Baumé, \$16 per ton of 2000 lbs.  
Sulphuric Acid 66° Baumé, \$25 per ton of 2000 lbs.  
Sulphuric Acid 20 per cent Oleum, \$28 per ton of 200 lbs. f.o.b. at manufacturers' works in sellers' tank cars.  
All strengths less than 66° Baumé shall be calculated from the price of 60° Baumé.  
All strengths above 66° Baumé (93.2 per cent H<sub>2</sub>SO<sub>4</sub>) shall be calculated from the price for 66° Baumé.  
In carboys, in carload lots, one-half cent per pound extra.  
In carboys, in less than carload lots, three-fourths cent per pound extra.  
In drums, any quantity, one-fourth cent per pound extra.  
Nitric Acid 42° Baumé 8½ cents per pound. f.o.b. manufacturers' works in carboys.  
In carboys in less than carload lots one-fourth cent per pound extra.  
There shall be no additional mixing charge for mixed acids, same being figured on the acidity content.

**Lansing Co. Receives Trailer Order**

LANSING, Sept. 30—The Lansing Co. has secured an additional Government contract for electric industrial truck trailers of the Reynolds type, thereby putting the company on a 90 per cent war basis. Seventy per cent is sent directly to the United States Government and 15 per cent is indirect. The remaining 10 per cent of the company's production will be devoted to equipment for industrial and commercial institutions. Under the new contract the company is to supply 400 trailers a week to the Government until the demands are supplied. The company now maintains three portable mills to supply lumber and timber for government use. One is located in a camp 15 miles west of Lansing, another near Holland, and the third near Ann Arbor. The company is now compelled to work over-time and has been devoting four nights a week to war work.

**Schacht Doubles Floorspace**

CINCINNATI, Sept. 28—The Schacht Motor Car Co. will occupy the large new extension to its plant in this city, by which it doubles its factory floorspace and considerably more than doubles its output by Nov. 1, after which 80 per cent of its production will be under contracts it now has with the Government.

**Liberty Carburetor Organizes**

The Liberty Carburetor Co., Detroit, has been organized by Jere McCarthy, president of the McCarthy Motor Sales Co., Ford distributor. The company will manufacture a special carburetor for Ford cars known as the Liberty.

**Airplane Plant for Chicago**

CHICAGO, Sept. 28—The Illinois Mfg. Association is negotiating for the erection of an airplane plant here. The estimated cost is \$50,000,000.

**More Room for France**

CLEVELAND, Sept. 28—The France Mfg. Co. has just moved into a new factory building on Berea Road.

**Naval Architects to Meet Nov. 14**

PHILADELPHIA, Sept. 28—The twenty-sixth general meeting of the Society of Naval Architects and Marine Engineers is to be held in Witherspoon Hall, Philadelphia, Thursday and Friday, Nov. 14 and 15. There will be a banquet at 7 p. m. Friday.

**Wisconsin Plates to Cost \$0.15½ a Pair**

MILWAUKEE, Sept. 30—The State of Wisconsin has contracted with the Schwab Stamp & Seal Co., Milwaukee, for 200,000 pairs of motor license plates for 1919 at 15½ cents per pair, the same price charged by this concern for the 1918 supply. Last year the requirement was 180,000.

## Current News of Factories

*Notes of New Plants—Old  
Ones Enlarged*

**Western to Make Own Trailers**

KANSAS CITY, Sept. 28—The Western Trailer Co., of which C. J. Welch is president, will take up the manufacture of a line of trailers. The company heretofore has been Western distributor of Fruehauf trailers, but hereafter will make its own. It is planned to produce a body for every line, including flare-board, stake and enclosed, canopy top, etc. The company is erecting a four-story building 60 x 150 ft., and will be in production within 90 days.

**Ford Considering Mexican Market**

DEARBORN, MICH., Sept. 30—Henry Ford & Son have closed arrangements with J. L. Mayfield, of Mexico City, Mexico, to supply him with 1000 Fordson tractors during the ensuing year for distribution throughout Mexico. He has been appointed Mexican representative, but will be privileged to send tractors to states bordering Mexico if the opportunity presents itself. This means that all the machines sent to him will not be distributed entirely within Mexico.

The current rumors that the tractor company has completed plans for the erection of a plant in Mexico are unfounded. The proposition is being looked into, however, and it is Ford's intention eventually to have a factory in that country.

The tractor plant is running at high speed, and is striving hard to attain a production of 200 tractors daily. The highest daily output was reached Sept. 27, when 191 machines were produced.

**Detroit Weatherproof Advances Price**

PONTIAC, MICH., Sept. 30—The Detroit Weatherproof Body Co. will advance its prices from \$97.50 to \$110 on Oct. 1.

**Dividends Declared**

The Hendee Mfg. Co., Springfield, Mass., has declared a quarterly dividend of 1½ per cent on its preferred stock, payable Oct. 1. Books close Sept. 20.

The Standard Woven Fabric Co., Framingham, Mass., has declared a quarterly dividend of 1½ per cent on its first preferred stock, payable Oct. 1. Books close Sept. 20.

The Hupp Motor Car Corp., Detroit, has declared the regular quarterly dividend of 1½ per cent on the 7 per cent cumulative preferred stock, payable Oct. 1 to stockholders of record Sept. 20.

**Oakland Starts on First Government Order**

PONTIAC, MICH., Sept. 30—Work has started this week at the Oakland Motor Car Co. on the company's first Government order. A large contract for two-wheeled kitchen trailers for the Aviation Section had been received several weeks ago. The capacity of the trailer is 1 ton, and when fully equipped is a complete field kitchen for 310 men. Stoves and ovens are mounted directly on the trailer, which is equipped with adjustable legs to balance it in horizontal position. None of the equipment is removed from the trailer when in use.

**Trailers from Grand Rapids**

GRAND RAPIDS, Sept. 30—The J. M. Case Trailer Co. is a new company in the motor truck industry which manufactures a complete line of all-steel semi and four-wheeled trailers of 3, 4, 6 and 10-ton capacity. The company also builds three sizes of pole trailers, 3½, 4 and 6-ton, and trailer chassis equipped with gravity steel dump bodies. The president of the new company is J. M. Case.

**Auto Body Gets War Order**

LANSING, Sept. 28—The Auto Body Co. has received a war order for truck bodies, the value of which is said to be approximately \$500,000. This is understood to be one of a number of body orders given or to be given by the Government to some of the body manufacturers who heretofore have done little or no war work.

**Chicago Dealer Develops Farm Light**

CHICAGO, Sept. 28—To supply complete automotive equipment to dealers for farm power, the Marmon-Chicago Co., Marmon and Hupmobile distributor, will market on a national scale a new product of its own, the Universal farm light and power plant, designed to supply complete electric light and power for the modern farm. Charles E. Gambill, for 17 years with the Marmon company, and president of the Marmon-Chicago Co., states that the Universal plants will be distributed entirely through motor car trade channels. The system is one which can be utilized not only for electric lighting but also is designed for use with other small power farm machinery, such as cream separators, milking machines, feed grinders, etc., and, in addition to the gasoline-electric outfit, the company will distribute nationally equipment of this sort, designed for the Universal plants. In addition the Marmon-Chicago Co. has taken on the distribution over limited territory of the Parrett tractor.

**Motor Truck Club Changes Name**

NEW YORK, Sept. 28—By way of eliminating misunderstanding regarding its aims and objects, the Motor Truck Club of America has changed its name to Motor Truck Association of America.

**Quartermaster Corps Contracts**

WASHINGTON, Sept. 30—The following list of contracts have been placed by the Quartermaster Department of the Army:

George W. Diener Mfg. Co., Chicago, gasoline cans, \$1000.  
Vacuum Oil Co., New York, Gargoyle cylinder oil, \$33,160.  
Standard Oil Co. of Indiana, Chicago, fuel oil, \$42,880.  
Prudential Oil Corp., New York, motor gasoline, \$54,000.

**Aircraft Bureau Contracts**

WASHINGTON, Sept. 30—The following list of contracts have been placed by the Bureau of Aircraft Production:

Hayes Mfg. Co., Detroit, cylinder jackets.  
Liberty Iron Works, Sacramento, spares for planes.  
Fisher Body Corp., Detroit, spares for planes.  
Iron City Products Co., Pittsburgh, engine spares.  
Chicago Metal Products Co., Chicago, piston pins.  
Splitdorf Electrical Co., Newark, spark plugs.  
Zenith Carburetor Co., Detroit, spares for carburetor.  
Wright-Martin Aircraft Corp., New Brunswick, engine spares.  
Bristol Co., Waterbury, Conn., venturi tubes.  
W. H. Mullins Mfg. Co., Salem, Ohio, cylinder water jackets.  
Watts, Stebbins & Co., New York, balloon cloth.  
Stewart Hartshorn Co., New York, tie rods.  
Wright-Martin Aircraft Corp., New Brunswick, engine spares.  
Willis-Overland Co., Toledo, engines.  
Western Electric Co., New York, fittings for antenna systems.  
A. Fisher Body Corp., Detroit, propellers.  
Wright-Martin Aircraft Corp., New Brunswick, engine spares.  
Duplicator Mfg. Co., Washington, commercial duplicators with supplies.  
Pittsburgh Steel Products Co., Pittsburgh, steel tubing.  
Bordentown Steel & Tube Co., Bordentown, N. J., steel tubing.  
Batesville Lumber & Veneer Co., Lawrenceburg, Ind., lumber.  
Louisville Point Lumber Co., Louisville, lumber.  
Koesse, Shoe & Schleyer Co., Cincinnati, lumber.  
James Cunningham & Sons Co., Rochester, balloon windlasses.  
Foxboro Co. (Inc.), Foxboro, Mass., air speed indicators.  
Splitdorf Electrical Co., Newark, engine spares.  
Kuena Radiator Co., Toledo, radiator spares.  
Candler Radiator Co., Detroit, radiator spares.  
Splitdorf Electrical Co., Newark, spark plugs.  
Curtiss Aeroplane & Motor Corp., Buffalo, spares for planes.  
Marlin-Rockwell Corp., New York, N. Y., boxing radiators.  
Pyrene Mfg. Co., Washington, fire extinguishers.  
Tennessee Valley Iron & Railroad Co., Colliwood, Tenn., locomotive and crane.

**Engineer Depot Contracts**

WASHINGTON, Sept. 30—The following list of contracts have been awarded by the General Engineer Depot, War Department:

Hercules Gas Engine Co., Evansville, gasoline and kerosene engines.  
Goodyear Tire & Rubber Co., Washington, rubber hose.  
Texas Co., South Washington, Vt., Texaco motor oil.  
Link-Belt Co., Chicago, locomotive cranes.

**Ordnance Department Contracts**

WASHINGTON, Sept. 30—The following list of contracts have been placed by the Ordnance Department of the United States Army:

Holt Mfg. Co., Peoria, Ill., tractor equipment.  
Nash Motors Co., Kenosha, truck equipment and truck chassis.

**Contracts**

R. M. Newbold, Washington, test and development of truck lighting, maintenance, and repairs on motor vehicles.  
Detroit Copper & Brass Rolling Mills Co., Detroit, brass rod.  
Warren Tool & Forge Co., Warren, Ohio, crowbars.  
Grant Motor Car Co., Cleveland, gun drawings.  
Fox Motor Co., Philadelphia, and Presto Machine Works (Inc.), Brooklyn, inspection gauges.  
Eiseman Magneto Co., Brooklyn, magneto breaker.  
Nash Motors Co., Kenosha, truck repair parts.  
Johns-Manville Co., H. W., New York, speedometers.  
American Brass Co., Waterbury, Conn., hinge pins.

**Ordnance Department Contracts**

WASHINGTON, Sept. 27—The Army Ordnance Department has placed the following purchase orders:

Four-Wheel Drive Auto Co., Clintonville, truck repair parts.  
Studebaker Corp., South Bend, forging and machining shells.  
Quartermaster Corps, New York, cup grease and gasoline.  
A. O. Smith Corp., Milwaukee, smoke and drop bombs.  
Ohio Trailer Co., Cleveland, trailers and equipment.  
Nash Motors Co., Kenosha, various truck equipment.  
Highland Body Mfg. Co., Cincinnati, truck bodies.  
American Axe & Tool Co., Glassport, Pa., bench axes.  
North & Judd Mfg. Co., New Britain, Conn., snap hooks and rings.  
Berg Auto-Trunk & Specialty Co., New York, fuse setter cases.  
Hindley Gear Co., Philadelphia, trench motor assembly.  
Detroit Copper & Brass Rolling Mills, Detroit, cartridge-case disks.  
White Motor Co., Cleveland, truck spare parts.  
Holt Mfg. Co., Peoria, tractor hand books.  
Ford Motor Co., Detroit, helmets.  
Motor Car Equipment Co., New York, portable electric motor.  
Hale & Kilburn Corp., Philadelphia, miscellaneous equipment for repair trucks.  
C. M. Hall Lamp Co., Kenosha, rubber and brass tubing.  
Plant Bros. & Co., Manchester, N. H., repair truck covers.  
Bljor Motor Lighting Co., Hoboken, adapters.  
Fisher Auto Top Co., Norwalk, Ohio, powder bags.  
Inter-State Motor Co., Muncie, tractors.  
Four-Wheel Drive Auto Co., Clintonville, towing hooks, water manifolds.  
Champion Ignition Co., Flint, spark plugs.  
The Lang Body Co., Cleveland, crating cars.  
Commerce Motor Car Co., Detroit, brown prints.  
Dodge Bros., Detroit, spare parts for truck chassis.  
Bastian-Blessing Co., Chicago, miscellaneous chests for supply trucks.  
Dunlap & Co., Edinburg, Ind.; Chas. T. Wilt Co., Chicago, truck chests.  
American Car & Foundry Co., Berwick, trailer bodies and spare parts.

**Planes Coming From Cincinnati**

CINCINNATI, Sept. 28—The Overmeyer Airplane Mfg. Co. has bought three acres of land at the West End and will at once begin the construction of a plant for the manufacture of airplanes. It will begin with three large contracts from the Government for war service and will be kept busy on Government and war work during the period of the war, but the plans of the projectors are to manufacture airplanes for commercial and private use following the close of the war. E. C. Drury, of Philadelphia, is interested in the company.

**Ordnance Purchase Order**

WASHINGTON, Sept. 18—Following is a list of contracts and purchase orders placed by the Ordnance Department of the United States Army:

Four Wheel Drive Auto Co., Clintonville, Wis., truck chassis spare parts.  
General Electric Co., Schenectady, N. Y., mobile repair shop equipment.  
Quartermaster Corps, Washington, D. C., automobile and motorcycles.  
White Co., Cleveland, Ohio, tarpaulins.  
Ward & Co., Washington, D. C., repair track tools and equipment.  
Goodyear Tire & Rubber Co., Akron, Ohio, tire repair material.  
Berg Auto Truck & Specialty Co., New York City, carrying cases.  
Quartermaster Corps, New York, N. Y., axle grease.  
The Four Wheel Drive Auto Co., Clintonville, Wis., truck repair parts.  
Quartermaster Corps, New York, N. Y., engine oil.  
Dodge Bros., Detroit, Mich., instruction books.  
Swineheart Tire & Rubber Co., Akron, Ohio.  
Berg Auto Truck & Specialty Co., New York, N. Y., dispatch cases.  
Federal Rubber Co., Cudahy, Wis., rubber cups.  
Cadillac Motor Car Co., Detroit, Mich., unit tractor power plant.  
The Williams Foundry & Machine Co., Akron, Ohio, clamps.  
Firestone Tire & Rubber Co., Washington, D. C., Indian Tire & Rubber Co., New Brunswick, N. J., solid tires.  
Federal Rubber Co., Cudahy, Wis., hand grenade plugs.  
Norman W. Henley Publishing Co., New York, N. Y., automobile repair books.  
Allen Motor Co., Fostoria, Ohio, recoil groups.  
Commerce Motor Car Corp., Detroit, Mich., alterations on trucks.  
Lansing Co., Lansing, Mich., trailer trucks.  
The Wheeler-Schebler Carburetor Co., Indianapolis, Ind., carburetors.  
The Baker H. & L. Co., Cleveland, Ohio, standard tractors and trucks.  
The Eiseman Magneto Co., Brooklyn, N. Y., magneto repair parts.  
Commerce Motor Car Co., Detroit, Mich., tire pumps.  
Empire Rubber & Tire Co., Trenton, N. J.  
Columbus McKinnon Chain Co., Columbus, Ohio, American Chain Co., Bridgeport, Conn., truck chains.  
Firestone Tire & Rubber Co., Akron, Ohio, cord tires and inner tubes.  
Goodyear Tire & Rubber Co., Akron, Ohio, United States Tire Co., New York City, tires and inner tubes.  
Locomobile Co. of America, Bridgeport, Conn., motor testing apparatus.  
Maxwell Motor Co., Dayton, Ohio, test of ordnance vehicles at S. A. E. convention, Dayton, Ohio.  
The Eiseman Magneto Co., Brooklyn, N. Y., magnetos.  
The Nash Motors Co., Kenosha, Wis., metal tool boxes.  
Fisk Rubber Co., Chicopee Falls, Mass.; Braender Rubber & Tire Co., Rutherford, N. J., tires.  
United States Tire Co., New York City; Hood Rubber Co., Watertown, Mass.; Goodyear Tire & Rubber Co., Akron, Ohio; The B. F. Goodrich Rubber Co., Akron, Ohio, solid tires.  
The Nash Motors Co., Kenosha, Wis., miscellaneous truck equipment.

**Navy Supplies Contracts**

WASHINGTON, Sept. 28—The Bureau of Supplies and Accounts of the Navy Department has placed these contracts:

Randolph & Baker, Sussex, New Brunswick, airplane spruce.  
S. H. White, Ottawa, Ontario, airplane spruce.  
Watson & Todd, Ottawa, Ontario, airplane spruce.  
A. C. Dutton Lumber Co., Springfield, airplane spruce.

**Marine Corps Contracts**

WASHINGTON, Sept. 28—The Marine Corps has placed contracts as follows:

Marathon Tire & Rubber Co., Cuyahoga Falls, tire casings and inner tubes.  
Standard Oil Co., of New Jersey, Baltimore, oil and gasoline.  
Nash Motors Co., Kenosha, spare parts for trucks.

**Cleveland Busy on War Work**

CLEVELAND, Sept. 28—Nearly all the industrial activity in Cleveland is war work. Practically every kind of war necessity is made in this city. The production of passenger cars is at low ebb and all the companies are working up their inventories preparatory to getting on 100 per cent war basis by Jan. 1. Cleveland's production is more diversified than any city of the United States.

The wood-working and castings industries are not very busy, but it is expected that the latter will be filled to capacity within a short time. The Government demands for wood-working lines being only a small percentage of the capacity of the industry, many of the plants will be obliged to convert their facilities to other activities or suspend operations entirely, as very little commercial demand along this line exists.

The White company is speeding up its production of the large Government order for Class A trucks, part of which was parceled out to the Pierce-Arrow, Peerless and Packard companies, each receiving an order for 3000. The Peerless company is tooling up to get into production.

The Grant Motor Car Corp. is experiencing some difficulty in obtaining material. The average daily output of passenger cars is fifteen and truck production is 150 a month. The company is cleaning up its inventory with the expectation of being on 100 per cent war basis by the first of the year. The erection of a large building in Findlay, Ohio, is being considered, although nothing definite has been determined.

The Jordon Motor Car Co. is balancing its inventory and expects to be on war work entirely by the end of this year. The F. B. Stearns Co. is busily engaged in turning out Rolls-Royce airplane engines, of which it produces six a day. Only two passenger cars are built daily. Approximately 75 per cent of the production of the Willard Storage Battery Co. is for the Government. The production of passenger cars at the Winton plant is slowly diminishing, the output now being five a day. War work takes the biggest portion of the facilities of the plant. The Chandler Motor Car Co. has been in production on its war tractors for a number of weeks with the resultant reduction of passenger cars.

The tests at Dayton of the new bombing plane made by the Glenn L. Martin Co. are proving that this new type of

plane is the best yet produced. The results thus far are very gratifying, but the company is not ready to make any public announcement until the tests have been completed. The 68-acre flying field adjoining the plant is rapidly being put into shape and six large hangars will soon be erected. Each hangar will accommodate two or three machines.

**Disclose Chevrolet-G-M Plan**

NEW YORK, Sept. 28—In the official circular being sent to the stockholders of the Chevrolet Motor Co., calling attention to the special meeting to be held in this city on Oct. 11, for the purpose of voting on a plan calling for distribution of its assets to the Chevrolet stockholders, it is pointed out that an arrangement has been made with the General Motors Corp. whereby fractional shares will be purchased by that corporation at the rate of \$112 a share for General Motors Corp. common stock. The arrangement calling for the sale of the assets of Chevrolet to General Motors was approved in writing by the holders of 571,437 shares out of a total of 641,098 shares outstanding.

**Call "Non-Essential" Laborers "Slackers"**

WASHINGTON, Sept. 28—Transfer of men from employment in "non-essential" industries by characterizing them as "slackers" is planned by the United States Employment Service. Community Labor Boards throughout the country have been notified by N. A. Smythe, Director of the Service, to prepare and have published lists of industries in which women can be substituted for men. It is expected that by this means the men who are working in non-essential industries will be shamed into transferring their activities. It is anticipated that this will result in a transfer of 500,000 men to war work.

**Pay Certain Regal Creditors in Full**

DETROIT, Sept. 28—All creditors against the Regal Motor Co., now in receivership, whose claims are secured by first mortgage gold notes of the company, will be paid in full, it is announced by the Securities Trust Co., receiver. It is estimated that unsecured creditors will receive from 20 per cent to 25 per cent of their claims. The public sale, together with the machinery taken over by the Government, amounted to \$541,347.25.

**Bicycle Makers to Conserve**

WASHINGTON, Sept. 28—Bicycle manufacturers will conserve about 2500 tons of steel by observing a conservation program effective Oct. 1, and outlined as a result of conferences between the manufacturers and the War Industries Board. In addition to saving this steel, which is one-third of the quantity consumed by the industry in the last 12 months, there will be additional savings of other materials, production will be simplified and capital tied up in stocks will be released. The results are to be secured through a substantial reduction in the numbers of types and models of bicycles, saddles, handlebars, rims, tires, sprockets, pedals, etc. The manufacturers will discontinue, wherever possible, the use of metal, rubber and leather. Partly fabricated materials can be continued for production provided that no bicycles are made later than Dec. 31, 1918, other than those provided in the new program. Rim manufacture will be confined to one clinch type, 28 x 1 9/16, one single tube type 28 x 1 7/16. Tires will be confined to one clincher type in two sizes, either 28 x 1 1/2 or 28 x 1 1/4, one single tube type 28 x 1 1/2 or 28 x 1 1/4. Manufacturers may use the different markings, treads, etc., which are provided by the rubber tire manufacturers in accordance with their conservation schedule.

**Ford Tractors Sent in Carloads**

DEARBORN, MICH., Sept. 28—Henry Ford & Son are now carrying out a uniform policy with all their distributors of sending them only carload lots of 300 tractors each. This permits a whole train load to go to one destination and eliminates railroad congestion somewhat. The tractors are unloaded at one point and distributed from there throughout the state. Four train loads, each bearing 300 tractors, were dispatched to each of the following states: Iowa, Kentucky, Indiana and New York. Train loads will be sent to other states as fast as production permits. The daily production of the plant averages 155 tractors now.

**Seven Deaths from Flying**

WASHINGTON, Sept. 28—Seven deaths resulted at flying fields in this country for the week ending Sept. 21, 1918, representing one fatality for every 2129 hours flown, or 171,320 miles of air travel.

# Stewart V-RAY SEARCHLIGHT

*A Real Searchlight—Not a "Spotlight"*

When you have occasion to use a searchlight, you want a *real* searchlight—not a "spotlight" with its small restricted "spot" of light.

You want a strong, powerful, all-revealing searchlight beam.

That is what you have in the Stewart V-Ray Searchlight. Its penetrating shaft of light shoots 'way down the road, revealing even the most distant objects.

The exterior design is particularly noteworthy. See how it stands apart—a thing of beauty. Observe how symmetrical it is. Note the design of the body; also the back.

It is beautifully finished with many coats of jet black enamel, baked on. And there is just a touch of nickel here and there to make the "tailor-made" appearance complete.

The Stewart V-Ray Searchlight harmonizes with the design of the modern automobile. Adds to its appearance. Looks like a built-in part of the car—not like a misplaced, re-vamped headlight.

It is scientifically designed. Made with a perfect parabolic reflector, which is silver-plated—not polished tin. Has a full six inch curved lens, instead of plain window glass.

A 3¼ inch reducing mirror, included at no extra cost, is located in the center of the back. It is not necessary to twist the light at an unsightly angle to use mirror. The switch is located conveniently so the hand finds it instantly in the dark.

The back is so formed that the hand grasps the light naturally, without cramping—and turns the light in any direction—up, down, right, left, front, or back—with ease. The case is absolutely dust and moisture-proof. A focusing device permits the use of any size bulb.

The bracket—an exclusive Stewart feature—not only permits turning the light in any direction, but also fits any windshield.

Both its handsome appearance and complete utility recommends it. It has high quality and finish all the way through. Its low price—\$5.00—is not an indication of quality, but a tribute to the Stewart Organization, which makes quality accessories at popular prices possible through large quantity production.

And so it is with all Stewart Automobile Accessories. Each, because of sheer merit and high quality, deserves a place in the equipment of every automobile.

Stewart Accessories are sold by leading accessory dealers, jobbers and garages everywhere.

## **Aircraft Program of 1917 Proves Successful**

**Complete Engine Program Then Decided Upon Has Not Been  
Altered—Bureau of Aircraft Production Since It Took  
Hold Has Not Altered Program or Started  
a New Line of Production**

By David Beecroft

**N**EW YORK CITY, Oct. 8—Having told last week how the Aircraft Board was purposely created without executive power, and how its mission was purely advisory, leaving all executive power in the hands of existing organizations in the army and navy, the time is opportune to analyze the program drafted during the summer and fall of 1917 for aircraft apparatus and note how wise were many of the decisions made at that time in view of the latest developments at home and at the front. Each month brings fresh conviction as to the judgment of our program of aircraft design, and while there have been many orders and counter-orders, not one organization was responsible for these and very frequently the cause for them did not rest with the army or navy or Aircraft Board, but with aircraft authorities in other countries.

The wisdom of developing a type of engine such as the Liberty and building it with six, eight and twelve cylinders has been justified and the complete program of this engine has not yet been entirely carried out. The fact that on Sept. 5, 1918, one year from placing of the first contract for the Liberty engine, 6000 had been manufactured in America and

delivered is the best proof of the selection of such an engine, especially designed for production. In August approximately 2250 of these engines were manufactured, and the production in September must have approximated 3000. We are rapidly approaching the time when we will have a daily production of 275 Liberty engines, or a monthly production in excess of 5000.

Some months ago when production of Liberty engines was being slowed up it was urged that a great error had been made in not starting the manufacture in the summer of 1917 of several types of European aviation engines of good standing at that time. While the manufacture of such was not decided upon it was given very careful consideration by the Aircraft Board in 1917. It was found that to manufacture some of the best types of European engines the price would approximate \$11,000 per engine. The best figure one big American manufacturer would quote on one of these engines was \$10,000. The Liberty engine of greater horsepower has been produced on an original contract price of \$6,000 which was later reduced to \$5,000, and it is more than possible these engines will be produced at a purchase price

of \$4,000. It is solely the design and suitability of it to American manufacturing practices and American factory equipment and organization that have made this low price possible. It could not possibly have been done on a foreign engine.

There has been a good deal of experience in America during the past year in manufacturing a foreign type aviation engine. An order was placed for the manufacture of the twelve-cylinder European type engine in June, 1917, the order being for 1000 of these, and in the middle of May, 1918, or 11 months after the placing of the order, only six of these engines had been delivered.

### European Design and American Production

The argument that European types of engines should be built without changing the design has been largely exploded in this case, as over 700 changes had to be made in this engine to meet manufacturing conditions in American factories. It is true this is not as many changes as were made on the Liberty engine, but considering that the European type was a standard tried-out product, the figures are indisputable evidence of the difficulty of manufacturing a European type in an American factory without modifying the design.

Those who had to do with the general framing of the aircraft program in 1917 are to be congratulated on many of the decisions made relating to the program. Practically everything they decided upon is being carried out, and scarcely a new thing has been started since the creation of the Bureau of Aircraft Production in May, 1918, when John D. Ryan was placed in charge of this. The program for manufacturing the Liberty engine was laid out complete. The contract for the 300 hp. Hispano-Suiza engine was approved. The manufacture of the LeRhône engine was started. The selection of the DH-4 and DH-9 planes was settled in the fall of 1917. Arranging for the development of the Caproni and Handley-Page bombing planes was under way last fall and in the early winter and experts to give the necessary assistance in developing these types were brought to this country. The Handley-Page staff arrived the last week of December, and the Caproni experts arrived in January. Arrangements were made for bringing LaPere, the well-known French designer, to this country to develop new designs and he arrived last December.

### Criticism of Senate Committee Must Be Withdrawn

With this record of achievement to the credit of those who took charge of our airplane program a year ago, and with practically nothing new started since the Ryan administration took hold, many of the statements of the recent Senate Committee Report must be discounted and many of the blames placed on the Aircraft Board must be withdrawn. In spite of not having executive power, but only being an advisory organization, the old board seems to have had a broad grasp of the situation.

It is opportune here to just refer to the general conception of aviation as held in the summer of 1917. At this time our Allies insisted on America meeting first of all the great requirements for mate-

rials. If America could give England and France materials out of which airplanes could be made that would be a big step in checkmating Germany. Our Allies had to have materials in order to carry out their airplane program. Consequently our first duty was that of supplying materials.

After this our Allies insisted on America supplying finished parts if they were able to do this after furnishing raw materials. Raw materials must come first, and finished parts afterward.

The third requirement was that we must supply trained men by way of aviators, mechanics, ground men and others to assist in airplane work.

With these three primary essentials supplied, our Allies took the view that if in addition America could manufacture planes, she should decide on the manufacture of those planes that could be produced in greatest quantities and which would be interchangeable so far as uses are concerned, that is, planes suitable for directing artillery fire, reconnaissance, photography, and other uses. It was undoubtedly this request on the part of our Allies which led to the selection of such a type as the DH-4 or the DH-9, which are well suited for a variety of uses, and lend themselves to production.

### Program of Great Significance

In view of this desire on the part of our Allies, the program as laid down on aviation a year ago becomes of greater significance.

This partly explains the delays which have taken place with regard to our program on building bombing planes, such as the Caproni or Handley-Page.

It was not until July, 1917, that the Handley-Page bombing plane started on its developing stages in England. At that time few were produced and England was just developing an interest in a bombing plane program. The first conception of possibility of destruction by a bombing plane dates from July, 1917, when the British Handley-Page made the trip from London to Constantinople and destroyed a Turkish war ship. This really decided the British to go ahead with the manufacture of such planes, but it was necessary to make a great many changes in design.

### America Urged Not to Produce Bombing Planes

At that time America was practically urged not to go into bombing plane production because the submarine menace was particularly acute and it was a grave question as to whether America would have shipping facilities to transport bombing planes if they were manufactured. In view of this there is little wonder that America should have considerably delayed its bombing plane program.

Later, in 1917, when the possibilities of building bombing planes were seriously considered there were unfortunate incidents that delayed matters. At this time Handley-Page had no working drawings suitable for beginning production in America. Three different sets of Handley-Page drawings were sent to America, the last arriving in December, 1917. It was planned to go into production and dies were made according to the first two sets of drawings.

all of which had to be destroyed when the third set arrived in this country. Some further dissension was created about this time due to a personal representative coming to the United States and endeavoring to sell the Handley-Page on a personal basis in spite of the fact that the U. S. A. had previously arranged to deal direct with the British Government on such matters.

In justice to the old board organization, which was largely drawn from the automobile industry, and to the manufacturers who endeavor to carry out

the orders placed by the army and navy, it must be stated that the change in board leadership has not resulted in any new policy with regard to our aircraft program. The Bureau of Aircraft Production has not started into production a single new type of engine or plane that the old board had not started. The Bureau of Aircraft Production has, as nearly as can be judged, consumed 3 or 4 months going over about the same ground that the old organization went over in 1917 and has apparently arrived at about the same conclusions.

## Accuracy Training Most Rigorous Test

**T**HE most rigorous flying instructions given to pilots, according to the War Department, is "accuracy training." This comprises turning the figure eight at angles of 60 degrees on short courses flying as low as 300 ft.

On an average field for this instruction there are three figure eight courses laid out, with eight markers, one in the center of each turn, one where the turn starts, one where it finishes and one at the outermost point. These are fixed points, never changed because of varying winds, though turns must be made in the direction which will come nearest to bringing them into the wind. All courses are so laid out that, should a forced landing be necessary owing to motor or other trouble, it will be possible to reach either the main field or some other open field suitable for safe landing.

A new man is first taken up by an instructor, who points out the courses, flies one of them, then has the student fly it. If any difficulty is developed in coming quickly into a 50-degree bank and holding it without either climbing, nosing down, slipping or skidding, or if turns are not made accurately over the points and wind drift properly overcome by "crabbing," the student has his trouble pointed out and is worked over until he can fly satisfactorily with an instructor.

Most of his work on eights is then done alone, in flights lasting 15 or 20 minutes, under the careful observation of the instructors and of all students not in the air. He is kept on eights until he can fly them almost perfectly alone. If any difficulty develops which he does not right after criticism, he is taken up again by an instructor. On eights, and field work as well, he must level off 150 to 200 ft, before a turn.

For climbing out of the field a square 1200 ft. on a side, marked by corner pylons and whitewashed side lines, is used.

The pilot must make banks at the corners as steep and sharp as he can with confidence—at least 45 degrees, preferably 60 degrees—and must hold his course accurately to the white ground line. The only exception is made on the first turn. When the wind is not head-on against the take-off, it may be difficult to make the first turn over the pylon 1200 ft. from starting and take-off with safety, and pilots are ordered never to attempt it unless sure of ample flying speed.

After four times around the field, a plane climbs to 1000 ft., makes sure that no others are taking off, flying the course, or landing, and does a one-turn spiral, aiming to stop on a white spot in the center of the field. Ample speed for safety, however, particularly on the last part of the spiral and straightening out for the landing at least 100 ft. above the ground, are insisted upon as of greater importance than merely stopping in the exact center of the field.

Three or four planes are usually sent off in series, timed so that no two will be over the same part of the course at one time. They must spiral down on the same order as they started, and each plane must start its spiral immediately after, but not until, the plane ahead has landed. There is a knack in the beginning of this spiral, and it takes time to acquire it. The engine must be cut off simultaneously with the banking of the plane, and the pointing of its nose down and the whole movement must be executed while the plane is directly over the white spot in the center of the field.

Emphasis is laid on the bearing of the accuracy stage work on a student's later work, either on the front or as instructor. A good flier must be able to make turns accurately and without losing altitude. After becoming proficient in 60-degree banks it is not a difficult matter for him to practice later at higher altitudes.

# Magnetism in Magneto-Generators

## An Analysis of Flux Changes Through the Armature Coil and of the Voltage Curve of an Ignition Magneto Based on Oscillograph Records

By Harry F. Geist, E.E.

THE one most important element in the make-up of a magneto-generator is its magnetic field, for it is upon the strength of this field, its distribution through the magnetic circuits of the machine and the manner in which this magnetism is shifted by the motion of the armature that the generating ability of the magneto depends.

The magneto as designed for ignition purposes performs three electromagnetic functions, namely, the generation of electric energy, the storage of energy and the dissipation of the energy in the form of a spark. In the case of the high-tension magneto, production of the spark involves a transformation of the energy to a very high potential.

How the machine will generate the electric energy that subsequently goes into the spark depends upon the amount of the magnetic flux that is interlinked with the windings of the machine, and upon how this interlinkage is changed by the changing relative position of the armature faces with the pole piece faces; while the manner in which the coil stores and utilizes this energy is largely dependent upon the circuit characteristics of the windings.

This article will be restricted to a study of the magnetic flux present in the magneto and of the manner in which it is affected by the armature rotation. The writer has employed an oscillograph as a means of making such studies.

Attention is called to Figs. 1, 2 and 3, illustrating in a diagrammatic way a conventional wound-armature type magneto. The armature is shown in three distinctively different positions with respect to the reversal of the flux through the coil, this reversal taking place twice for each revolution. These positions are, respectively, 75 deg., 90 deg. and 105 deg. from the horizontal armature position. The arrow denotes the direction of rotation assumed. The diagrams show the magnets with an assumed polarity, the pole pieces conforming to the machine bore, and the armature with its winding, one turn of which is shown in section, and indicates the direction in which current would flow if the circuit were closed.

For this discussion, the winding is considered open circuited, so that the distribution of flux and the flux changes will respond naturally to the true changes in the magnetic path as the armature revolves and will not be disturbed by the reactive forces that would accompany closed circuit currents.

The diagrams also show the flux distribution through the armature as fed from the pole pieces in amounts designated by  $\phi$  expressed in maxwells, the standard unit of magnetic flux. This distribution shows the flux that flows through the coil core proper and the

flux that is by-passed from the coil by the armature faces in their proper proportions for each position, as calculated from data to be presented later. Inasmuch as the armature is assumed to be continually revolving, there will be a continual changing of the flux distribution as indicated by the lines marked  $d\phi/dt$ , which express the actual rate of flux shift and its direction, the unit of rate being one maxwell per second. These rates of shift were produced by an armature rotation speed of 600 r.p.m.

A study of the figures shows that in Fig. 1 most of the flux passes down through the coil, as indicated by the heavy dotted lines, and that it is being shifted out of its interlinkage with the coil to the path presented by the armature faces by-passing the coil.

Fig. 2 shows the armature in the position where its faces bridge the opposite pole piece tips, and in which position under ideal conditions all the flux would be excluded from the coil, but owing to the eddy currents and hysteresis of the iron that carries the flux, the flux is slightly delayed in being shifted from the coil core.

Referring now to Fig. 3, it is seen that the flux is here practically all flowing through the coil core again, but that it now flows up through the core in the opposite direction from that in which it flowed in Fig. 1, and, also, that the flux continues to be shifted into the coil.

In order that the electromotive force generated during the armature change will be of the same polarity for the positions of the armature shown, the shifting of the flux must always be in the same direction with respect to the coil. In the diagrams this condition is shown to be fulfilled in that the changing flux, as represented by the lines  $d\phi/dt$ , is passing downward on the left-hand side of the coil and upward on the right-hand side of the coil for all three diagrams.

Thus one varying impulse of e.m.f. is generated as

Figs. 1, 2 and 3—Diagrammatic illustrations of a conventional wound-armature type magneto, with the armature in three different positions with respect to the reversal of the flux through the coil

the armature makes one complete half turn, starting from its horizontal position, and duplicates its performance with an impulse of opposite polarity as it completes the revolution.

It is very important to notice at this time that during the first quarter of a revolution practically all of the flux is shifted out of interlinkage with the coil, and that for the succeeding quarter of a revolution this same flux is thrown back into interlinkage with the coil, the passing out and back into interlinkage following each other so closely that one continuous effect is produced. It is also important to notice that the flux, in being shifted, has two paths to follow during shift. These two facts, including the double use of the magnetic field and the double path for flux shift, combined with the shortness of the magnetic path necessary, are no doubt responsible for the fact that this type of magneto is easily the most efficient type of generator for magneto design.

In order to analyze the magnetic phenomena of a magneto in both a quantitative and qualitative manner, it is only necessary to study the manner in which the e.m.f. is generated as the armature revolves to produce the flux shift. The theory of this generation is as follows:

### Theory of E. M. F. Generation

It is well known that when magnetic flux is shifted from interlinkage with a coil of wire, or vice versa, an electromotive-force is induced in the coil. The simplest condition is that of the open circuit e.m.f., as with an open circuit the reactive forces due to electrical currents do not have to be taken into consideration.

This e.m.f. will be determined by the law according to which an e.m.f. of one volt will be generated at the terminals of a coil if a magnetic field is caused to be shifted in its interlinkage with the coil at the rate of 100,000,000 turn-maxwells per second.

If  $e$  designates this e.m.f.,  $N$  is the number of turns in the coil;  $\phi$ , the flux in maxwells, and  $t$  the time in seconds, then this law can be expressed in the form of the following equation:

$$e = \frac{Nd\phi}{10^8 dt} \quad (1)$$

Fig. 5—The o.c. voltage wave is a reproduction of the oscillogram shown in Fig. 4

Fig. 4—Oscillogram of the open circuit e.m.f. wave of a low-tension magneto of the conventional wound-armature type

In this equation  $d\phi/dt$  expresses the rate of flux change. Equation (1) can be transformed to read

$$\frac{d\phi}{dt} = \frac{10^8 e}{N} \quad (2)$$

giving the rate of flux change at any instant, or to read

$$d\phi = \frac{10^8 e dt}{N} \quad (3)$$

thus forming an expression for the amount of flux shifted during an infinitely small interval of time  $dt$ . By a summation of a series of consecutive intervals  $dt$ , taken over a complete cycle of flux change, the total amount of flux involved in the change can be ascertained.

It is therefore evident that any method that makes it possible to measure the e.m.f. induced in the magneto coil as it varies with the motion of the armature makes possible an analysis of the magnetic field of the machine, by the use of equations (1), (2) and (3).

The oscillograph offers a very simple and direct method of graphically measuring the voltage wave of the magneto, giving as it does a photographic record of the voltage variations for any period of time desired.

### Analytic Measurements

In Fig. 4 is illustrated an oscillogram of the open circuit e.m.f. wave of a low-tension magneto of the conventional wound-armature type. This machine is one of standard make and good design, and has the following physical dimensions that have a bearing upon its electromagnetic performance.

Its armature has an outside diameter of  $1\frac{3}{4}$  in. and is wound with 566 turns of No. 22 wire. The active bore depth of the machine is  $2\frac{3}{4}$  in., with a clearance of 0.004 in. between the rotor and the stator, and the overlap area of the armature tips upon the field pole tips for the vertical position of the armature is 0.327 sq. in. The weight of the magnets is 3.6 pounds.

In obtaining the oscillogram shown in Fig. 4, the armature was revolved at a speed of about 600 r.p.m.

Referring to the oscillogram, the arrow indicates the sequence of events along the record; the

upper curve represents the open circuit e.m.f. wave of the magneto for about one complete revolution of the armature and shows how the e.m.f. rises to a peak corresponding to a value of 53.2 volts during a small part of the revolution and then drops off as rapidly; and the lower curve shows a 60-cycle voltage wave that is practically sinusoidal, serving as a time calibration of the oscillogram, in that the distance between two similar points on the wave represents a period of 0.01666 second.

On this 60-cycle wave may be seen a little irregularity that locates the vertical line marked "Vertical Center Line of Magneto," and indicates the vertical armature position with respect to the open circuit e.m.f. wave generated in its coil. This small irregularity was produced by including a battery and coil circuit, of the kind commonly used for battery make-and-break ignition, in the 60-cycle circuit, so arranged as to be automatically short circuited and then opened at the instant the armature reaches its vertical position, so that the inductive kick voltage produced by the choke coil is superimposed upon the 60-cycle wave.

It is evident that by this combination of the e.m.f. wave of the magneto taken simultaneously with a 60-cycle timing wave that indicates the position of the armature, the value of  $e$  for any armature position can be easily obtained from Fig. 4 and that by the use of the data available in the oscillogram, in connection with equations (1), (2) and (3), a very complete analysis of the magnetic phenomena of the machine is possible.

Attention may be called to the fact that the maximum or peak value of e.m.f. does not occur at the instant the armature reaches its vertical position. Under ideal conditions it would generate its maximum voltage at this instant, but the shifting of the magnetism in the iron at a speed of 600 r.p.m. sets up eddy currents and hysteresis that cause the peak of the wave to be delayed slightly, as previously pointed out. These losses in the iron, of course, are greatest at higher speeds of rotation, so that the delay of the maximum is also greater.

### Calculations

A check-up for one complete revolution of the armature shows the time required to be about 0.10 second, but the results desired can be obtained from one-half the cycle of the machine, which corresponds to 0.05 second.

If the time ordinate of the e.m.f. wave of the machine is divided into 100 equal parts, each part representing an interval of 0.0005 second, and the value  $e$  is tabulated for each part, it is possible to tabulate simultaneously with these values of  $e$ , by the use of equation (2), the rate of flux change  $d\phi/dt$ , and since each of these divisions represents an armature position that can be determined, it is evident that the rate of flux change for any armature position is determinable.

Further, by the use of equation (3) it is possible to calculate the flux in maxwells shifted during each interval, so that by adding the amounts of flux shifted for all intervals the total amount of flux shifted with respect to the coil is obtained. Such a summation derived from the oscillogram, Fig. 4, gives the total amount of flux as 60,720 maxwells.

It must be remembered that the flux is first shifted out of interlinkage with the coil and then back into interlinkage with the coil, so that the actual amount of flux present in the machine is only half of 60,720 maxwells, or 30,360 maxwells.

An approximation of the above result may be obtained by considering the entire half revolution of the armature as one interval of time  $dt$ , so that  $d\phi$  will then give the total amount of flux shifted for the half revolution. For this approximation it is necessary to take the

numerical average value of  $e$  for the half revolution. The average value of  $e$  for the oscillogram shown may be obtained by the use of a planimeter or by taking the average of a hundred equally spaced values. This value was found to be 6.72 volts, which, substituted in equation (3), gives

$$d\phi = \frac{10^8 \times 6.72}{566} \times 0.05 = 59,360 \text{ maxwells}$$

shifted with respect to the coil for a half revolution, and checks very well with the 60,720 maxwells obtained by the step by step summation process.

To illustrate the method of calculating the flux shift, as well as the maximum rate of flux change in this machine, the maximum or peak voltage value is substituted in equation (2):

$$\frac{d\phi}{dt} = \frac{10^8 \times 53.2}{566} = 9,399,300 \text{ maxwells per second.}$$

In Fig. 5 the o.c. voltage wave is a reproduction of the oscillogram of Fig. 4 and the curve marked "Flux Through Coil" is obtained by subtracting the flux shifted for each of the 100 intervals of time from the maximum flux through the magneto, until none is left, and then adding the flux shifted until all the maximum is again obtained. The distance between the zero flux line and the maximum flux line is thereby divided into two parts, of which the lower represents the amount of flux flowing through the coil, and the upper, the amount flowing through by-pass paths, so that the diagram makes possible a complete analysis of open circuit flux distribution for any armature position. The rate of flux shift  $d\phi/dt$  will always be exactly in proportion to the open circuit voltage and can be obtained by multiplying the value of  $e$  by the constant 176,500, as seen from equation (2).

The values of flux distribution and shift given in Figs. 1, 2 and 3 were obtained from diagram, Fig. 5.

Another item of interest in this connection is the form factor of the voltage wave generated:

$$\text{Form factor} = \frac{\text{Effective value}}{\text{Average value}} \quad (4)$$

The effective value is the value indicated by an ordinary voltmeter and is also the value received by taking the square root of the average of a large number of values of  $e$  taken at equal intervals over the wave and squared. This square root of the mean squares or effective value taken by means of an ordinary voltmeter for an armature speed of 600 r.p.m. was 13.0 volts, while calculations based on Fig. 4 give the value as 12.82, which is a very good check. Therefore,

$$\text{Form factor} = \frac{12.82}{6.72} = 1.91.$$

From this form factor it is possible to calculate the average voltage received from a magneto over quite a range of conditions without the use of an oscillograph, because the form factor is dependent almost entirely upon the physical dimensions of the armature and the field pole pieces and their co-relation.

**BAUXALITE** is a non-ferrous metal having a specific gravity slightly greater than that of commercial cast aluminum. Its specific gravity is 3.2. According to reports of tests on hand it has a tensile strength of from 30,000 to 35,000, and compression, transverse, and torsion strength of 125,000, 87,000 and 60,000 lb. respectively.

It is said to be easily machined at high speed without the use of a lubricant. It is claimed for it that while it may be plated in any metal color required, it can be polished to a silver finish by the usual simple methods and will not corrode.

# Tractor Activities in Northern Ohio

Industry Early Developing Into a Specializing or Assembling One—Parts Makers Increasing—What the Various Companies Are Doing

By P. M. Heldt

**I**NDIANAPOLIS, IND., Oct. 4.—Northern Ohio has been a center of the agricultural implement industry, particularly the traction engine and thresher industry, and since the "gas" tractor is closely related to the steam traction engine, and is, in fact, rapidly replacing it, it is no wonder that we find the tractor industry well represented in this district.

There are essentially two classes of firms engaged in the tractor business in Ohio, one with implement antecedents, the other composed mainly of men who were formerly or are still connected with the automobile business. The former are for the most part located in the smaller towns, while the new organizations, composed of automobile men, seem to prefer the large manufacturing cities.

The tractor industry is developing early into a specializing or assembling industry, and besides tractor manufacturers we find in the district mentioned a good many firms that supply complete parts to tractor makers.

The writer has just made a trip through the northern part of the state, starting at Cleveland and working in the general direction of Indianapolis, calling on all firms in the business located in this territory.

## Cleveland Expanding Rapidly

In Cleveland we have in the Cleveland Tractor Co. one of the largest firms in the industry. The Cleveland creeper type tractor, although it has been on the market only a little over one year, is already so well known that it requires no description. The firm occupies a new and modern plant at Lamb and Euclid Avenues, rather remote from the center of the city. In fact, it is beyond the urban street railway service and the firm operates a motor bus between the terminal of the street car line and its plant, which runs all day and carries people to and from the plant free of charge.

During the past summer the company moved into an addition to its plant, a single-story structure measuring 182 x 444 ft. The original plant is now used almost exclusively for office purposes, the various factory departments, such as machine shop, heat treating and assembling departments, having been moved into the new building. At present the company employs a force of 884.

Its output during the month of August was between 600 and 700 tractors, and it is hoped shortly to get the production up to 1000 tractors per month. In this connection it must be remembered that the engine, which forms a very considerable part of the whole tractor, is manufactured in the Weidely plant in Indianapolis.

The Cleveland tractor is a two-plow outfit and, being of the creeper type, is specially adapted for use in districts where the ground has to be worked while in a soggy condition or where the soil is sandy. I asked Mr. Drysdale, the advertising manager, whether there was any tendency toward a seasonal business in tractors, and he replied that they had not been able to observe this so far; there probably would be if only one section of the country was considered, but where a national business was done, one part of the country made up for another.

A number of improvements have recently been made in the mechanical construction of the tractor. Thus, the pins of the track are now surrounded by hardened-steel rollers, which engage with the teeth of the driving sprocket, whereby the life of the sprockets is greatly increased. Timken roller bearings are now used throughout the tractor, and a sort of roof shaped guard of sheet metal is placed on the track frame, on which the dirt carried up by the track falls and is carried off. The Cleveland company employs the movable assembling method in what is probably its simplest form, there being a track on the floor, consisting of two channels with the open side up. On this track there are wheeled trucks, on which are placed the frames of the tractors, to which the other parts are added as the trucks move along.

## Craig Tractor a Newcomer

A new concern in the tractor business in Cleveland is the Craig Tractor Co., which has just been incorporated under Delaware laws, with a capital stock composed of 3000 shares of 7 per cent cumulative preferred stock of a par value of \$100 a share and 3000 shares of common stock without par value. While the charter has been issued, at the time of the writer's call, the application for permission to issue stock had not yet been acted on. Development work for this firm is

*The Indiana tractor is adapted to haul any farm implement which requires three horses to draw it*

*Craig tractor plant in course of erection. This picture was taken Aug. 29, 1918*

being carried on in a leased building in Cleveland, but a new plant has just been erected for the firm in Euclid Village, just outside of Cleveland, by the Austin Company.

Harry Dwight Smith, president of the Fuller & Smith advertising agency, is president; Norman Craig, also of Fuller & Smith, vice-president and general manager; Arthur Judson, (Fuller & Smith) secretary and Roland T. Meachem, investment broker, treasurer. Other directors include Heman Ely, secretary of the Timken Roller Bearing Co.; H. J. Porter, special representative in Detroit of the Timken Roller Bearing Co., and Charles P. Hine, a Cleveland attorney.

The preliminary program of the company called for a production of 1200 machines during the first year. The purpose is to turn out a high-grade tractor, which, as Mr. Craig expressed it, would occupy in the tractor field about the same position as a Cadillac car occupies in the automobile field. While it is realized that such a tractor will cost considerably more than the farmer has been accustomed to pay, it is believed that the increased reliability and greater satisfaction derived from the use of such a machine will more than make up for the increased first cost. The new plant referred to is the Austin company's No. 1 design, measuring 60 x 180 ft. A full description of the Craig tractor, which was designed by John Dietrich, formerly chief engineer of the Republic Motor Truck Co., will appear in another part of AUTOMOTIVE INDUSTRIES.

#### J. T. to Have New Model

The J. T. Tractor Co., which occupies premises at 5810 Euclid Avenue, has been engaged in the development of a creeper-type tractor for some time. It has completed two successive models, which have been tried out in practical work, and is now building a third model, which will be completed within a few weeks and will embody a number of improvements over the previous models. It is intended to use the chief model, manufactured by a concern newly organized at Port Huron, Mich., by Harry Erd, formerly of the Erd Motor Co.

The tractor is to be a three-plow machine and will be equipped with a four-cylinder  $4\frac{1}{2}$  x 6 in. engine. A feature of the creeper construction is that the driving sprocket engages with both ends of the track pins. There are 32 shoes in each track, and each shoe has only a single gripping projection, this having been found preferable to the double projection, because with the latter construction the space between the two projections on each shoe will fill up with dirt, which will adhere to it, thus making the projections partly ineffective. A Detroit Gear & Machine Co. three speed transmission is used. This is similar to the same company's automobile transmission, except that the intermediate speed is the direct drive and the high speed is geared up. The three speeds of the tractor are  $1\frac{1}{4}$ ,  $2\frac{1}{2}$  and 5 m.p.h. This new model will be known as Model N and will be rated as a 16-30-hp. or three-plow tractor. Its weight will be about 6000 lb. Kerosene fuel will be used, the company also having developed a kerosene carbureter, which is being manufactured also for the general market and is now in regular production.

A sectional view of the carbureter is shown herewith. It is of the type in which the fuel nozzle is completely closed when the engine is not running. This permits of using the carbureter without a float if so desired, and it has been successfully used on tractors in this way. In the illustration, however, the carbureter is shown with a float. The float is of the spun metal type and acts on the float valve through a pair of balance levers. The kerosene flows from the float chamber through a communicating passage to the spray nozzle, in the top of which is a taper metering valve. This valve is carried by a cylindrical block of metal, which forms the plunger of a dash pot. Connected to this plunger by a number of radial arms is an air valve which when the carbureter is not in operation completely closes the space around the spray nozzle. The ends of the air valve or ring are tapered out. When the engine is started up and a suction is created in the upper part of the carbureter, the air valve is lifted, and with it the fuel valve.

It will be noticed that the fuel valve proper is held in a brass holder, which has a tapering seat in the mouth of the spray nozzle. The greater the suction, the more the air valve and the fuel valve will lift. Owing to the tapering end of the valve holder, the kerosene drawn out of the spray nozzle spreads over the upper surface of the metering valve seat and the part surrounding the nozzle, referred to as the mixture adjusting slide, and as it reaches the edge of this surface, it is taken up by the air coming up through the restricted passage between the mixture-adjusting slide and the air valve. At this point of the air passage a sort of Venturi effect is produced, which results in a very strong atomization of the fuel. The dashpot connected to the air valve and metering valve prevents any fluttering of these parts when the throttle valve is suddenly opened or closed.

For starting, a rich mixture can be obtained by moving the mixture-adjusting slide upward by means of a lever and link connection to an operating device located convenient to the driver. Vaporization of the kerosene is effected by preheating the air drawn into the carbureter by passing it through an air heater combined with the exhaust manifold. In using this carbureter on the J. P. tractor, it has been found that the kerosene can be turned on after running on gasoline for a distance of 400 ft., this, of course, referring to full load operation. The J. P. kerosene carbureter is manufactured in 1,  $1\frac{1}{4}$ ,  $1\frac{1}{2}$ ,  $1\frac{3}{4}$  and 2-in. sizes.

#### Standard Parts Has New Wheel

The Standard Parts Co., of Cleveland, which manufactures a great variety of parts for automobiles and motor trucks, also supplies numerous parts to tractor makers, including springs, gear blanks, Bock roller bearings, bands for built-up wheels, and steel tubing, either straight or bent according to specifications. The company has developed a special design of tractor driving wheel having an ordinary plain rim, with quick detachable lugs. The wheel has solid round spokes, which are welded to the hub and rim. Owing to the pressure of war work, it is very doubtful whether this wheel will be put in production while the war lasts.

e K. W. Ignition Co., manufacturer of magnetos and ignition parts, supplies magnetos to a great many tractor manufacturers. It was the originator of the impulse which is now almost universally used on tractors having magneto ignition. This company is also supplying magnetos for Government work, and this, in connection with its ignition replacement business, keeps it quite busy.

#### Has Big Gas Tractor Maker

Marion, Ohio, is located the Huber Manufacturing Co., one of the largest manufacturers of gas tractors in the state. The firm has been building steam traction engines for threshing for 40 years and it took up the gas tractor at a very early date. In fact, so far as it has been able to learn, it was the first gas tractor in the country, and the writer was shown a clipping from the *American Thresherman*, of June, 1911, according to which the Ferguson Implement Co., of Kansas City, Mo., who at that time was acting agent for the Huber company, was exhibiting what was referred to as a gasoline engine, made by the Huber company, which was mounted on a gas tractor, with a single cylinder upright engine. Referring to the machine, the paper went on to say that it was claimed to be a powerful puller and very economical in operation, as this fuel, gasoline, is cheaper than coal in producing a good power. The Huber company also has a letter from F. J. Collinson, of Willmar, Minn., stating that in November, 1898, I bought one of your gas tractors, No. 101. It was the first gas tractor ever landed in old Illinois. People came from miles to see it work. It was a single cylinder hot tube engine. It had only the old hot tube for ignition and worked with a match."

Barlow, of the Huber company, states that this was the first or the second machine that they turned out. They began with either No. 100 or No. 101. They put through a lot of thirty machines, but later gave up their early manufacture. However, they continued thinking of tractors and developing their ideas until they got into production in 1910. For some years they manufactured quite an extensive line and adopted the slogan: "A tractor to fit every farm"; but later on they reached the conclusion that the advantages of standardization and quantity production outweighed those of a well sounding slogan, and they are making only a single model, a three plow machine. During the past year the Huber company turned out approximately 2000 tractors, and material has been purchased for 3000 for the coming year, but owing to the recent action of the War Industries Board, the program may have been curtailed.

#### Aultman-Tailor Small Model

Aultman-Tailor Machinery Co., located at Mansfield, Ohio, manufactures a wide line of agricultural machinery, and has been in business for 54 years. A number of years ago it took up the gas tractor and now produces four models, at 15-30, 18-36, 25-50 and 30-60 hp. The smallest model recently brought out only quite recently and is equipped with a single cylinder engine, while heretofore the company has manufactured all parts of the tractor itself, with the exception, of course, of such parts as magnetos, carbureters, etc. During the past year the demand for tractors was unusually strong, and many more could have been sold than it was within the capacity of the company to produce. The actual output was between 600 and 700 tractors. The company's program for the coming year has not yet been laid down, as its year begins Nov. 1.

Shelby, the Shelby Tractor & Tractor Co., which was organized about a year ago, has completed a 3-ton truck model and is working on another. Owing to the fact that the company is engaged in producing to its full capacity, it is not likely that tractor production will be started upon before the end of the war. The tractor which is now being designed will have a 4½ x 6 in. engine, a Foote Bros. transmission, Bierman clutch and steering gear. It will be rated as a 2-3 plow tractor and will weigh about 4700 pounds.

Shelby Tractor & Tractor Co. was organized as a corporation in March, 1918. It took over the properties of the Arbenz Motor Car Co., Cleveland, and of the Standard

Section views of J. T. kerosene carburetor

Manufacturing Co., Shelby, Ohio. W. R. Kerr is president and general manager; S. R. Feil, vice-president; W. J. Bailey, secretary, and A. A. McCormick, treasurer. Messrs. Feil and Bailey are not active in the affairs of the company, however.

The Ohio Manufacturing Co., Upper Sandusky, Ohio, manufacturer of the Whitney two-plow tractor, which was described in *AUTOMOTIVE INDUSTRIES* some time ago, is working on a lot of 300 of these tractors, but has been much delayed, owing to inability to get material in promptly. The company was formerly engaged in the agricultural implement business, but for several years past manufactured a single cylinder tractor, which was marketed through the International Harvester Co. About a year ago the company began to develop its present tractor, which is equipped with a Gile, two cylinder engine, of the opposed type.

#### Delays Caused by Shortage of Angle Shapes

The writer was told that the delays have been especially in angle shapes and efforts have been made to obtain missing material by buying job lots.

A somewhat novel design of tractor has been manufactured during the past year at Findlay, Ohio, by the Star Tractor Co., which occupies a new concrete block factory, 50 x 156 ft. Heretofore the tractor has been known as the Star, but recently a sales arrangement was entered into with the Indiana Silo Co., of Anderson, Ind., and hereafter the machine will be known as the Indiana. The writer was told that a reorganization has just been effected, which will result in greatly increased production, but details could not yet be given out. The original company was organized in June, 1917, with a capital stock of \$100,000, J. L. Bicknell being president; C. A. Schubert, vice-president, and C. A. Jordan, secretary and treasurer. About 160 tractors have been built to date.

#### Indiana Tractor

The Indiana tractor has a rating of 5-10 hp. and is a 1-2 plow machine. The strong point made in connection with it is that it can be used for any farm purpose for which three horses are now used. It also has a very high ground clearance and therefore is especially suitable for cultivating. The tractor is equipped with a four-cylinder, 3½ x 4½-in. Leroi engine, with Atwater Kent ignition and Kingston carburetor. Gasoline is used as fuel and a supply of 7 gal. can be carried.

The engine is fitted with a governor, which maintains its speed at 950 r.p.m. The final drive is by chain and four speeds are obtained by interchanging the sprocket pinions, viz.: 2.1, 2.4, 2.7 and 3.6 m.p.h., the first two being for plowing and the last used for road work and in hauling a binder.

The machine bears some resemblance to the Moline Universal, in that the front wheels are the steering and driving wheels, steering being effected by swinging the front truck around relative to the frame, by means of a gear sector and pinion. The two rear wheels simply steady the tractor and carry practically no load. The weight of the whole machine is only 1700 lb., or about that of one horse.

# Recent Enemy Airplane Activities

Some New Planes and Engines Concerning Which Information Has Been Obtained Through Prisoners and From the Enemy Press

**W**HILE information concerning German airplane activities is very difficult to obtain, some seeps through by way of captured prisoners as well as through other channels.

Recently there was captured a two-seater L. V. G. type of German plane from which some interesting information was obtained. It has fitted a 220-hp. Benz engine having aluminum pistons and an adjustment on the carburetor for flying at high altitudes; Bosch magnetos of the Z. H. 6 type are fitted.

The L. V. G. is a biplane weighing 2095 lb. empty and built for a permissible load including full tanks of 947 lb., giving a total weight of 3042 lb. The span of the top plane is 42 ft. 6 in. and the chord 5 ft. 3 3/4 in. The lower planes each have a span of 18 ft. 8 1/2 in. and a chord of 4 ft. 7 1/2 in.

The wings are of wood with main spars of box type construction covered with fabric. The ribs consist of spruce flanges and solid three-ply webs. Wooden compression members are used. The propeller consists of nine laminations of ash.

A new type of German single-seater biplane is the Siemens-Schuckert, which uses an eleven-cylinder rotary engine with a four-bladed propeller approximately 7 ft. 6 in. in diameter. The engine of 160 hp. is fitted to the front of the fuselage and has a spider around the fuselage permitting a bearing to be fitted behind the propeller.

The upper plane has a span of approximately 30 ft. and there is a gap of 5 ft. between planes. The chord of the upper plane is 6 ft. and that of the lower plane 4 ft.

The fuselage, of streamline design, is short and deep. Ailerons fitted on both planes are partly balanced. The upper ones are larger than the lower ones and extend further along the plane toward its root.

Another new type of German aircraft is the Benz two-seater biplane, and there are reports that Benz is also building single-seater planes.

There seems to be a tendency in Germany to return to the monoplane for certain uses. As near as can be learned, there are two types of monoplanes in existence in Germany, namely, the Junker, with a stationary engine, and the Fokker, with the rotary engine.

Monoplane-seaplanes have been reported operating on the North Sea. These were supposed to be Brandenburgs. The fuselage is above the wings and not fitted with armor. These

monoplanes are said to have a speed of 100 knots per hour and a flying capacity of 5 hours.

The new 200-hp. Opel engine is a six-cylinder type with bore of 145 mm. and a stroke of 190 mm. It is fitted with two carburetors and has the inlet pipe water-jacketed. Dual ignition is fitted, and the weight empty, including propeller boss and exhaust pipe, is 726 lb.

There are reports of a new 190-hp. Rapp stationary engine. The Maedler Engine Co. is one of the new German organizations which is expected to manufacture an engine of this name. It is a single-cylinder type which is reported to develop 160 hp.

## Fliers Learn Air Acrobatics Quickly

WASHINGTON, Oct. 7—Airplane acrobatics, contrary to popular belief, are learned quickly by fliers. In fact, according to an announcement made by the War Department, fliers who loop the loop at 4000 ft. altitude, who do nose dives, side slips and the other twirls and stunts learn them in 8 hours or do not learn them at all. Cadet fliers are given the instruction in acrobatics for the end of their training and after they have secured complete control of their planes. This is necessary so that they learn the knack of throwing the machines in and out of the whirls and loops.

Great care is taken in choosing instructors for this work and in selecting the planes. Expert riggers are assigned to check the alignment of the planes after each flight. Mechanics go over the engines just as carefully. At Kelly Field there is a special stage set for the instruction, and to insure safety for the cadets and their instructor all planes not engaged in acrobatic instruction are required to keep entirely away from the territory over which the stunts are being performed.

No student or instructor is allowed to stunt under 2000 ft., and practically all of the work is done between 2000 ft. and 4000 ft. When a student reports for instruction in acrobatics he is assigned to a teacher who takes him up and performs the required stunts. The student is then given control and directed to repeat the maneuver. After the third or fourth time he is usually able to perform alone. However, in no instance are the students allowed to fly alone until they show themselves well qualified.

*Fokker monoplane shot down behind the British lines*

# New White Trucks with Double-Reduction Axles

## Unit Power Plant and Transmission Brake

*Components of the double reduction drive now used in the White 3 and 5-ton trucks and the method of applying the principle*

**D**DOUBLE-reduction axles have taken the place of chain-drive axles in the new 3 and 5-ton trucks of the White company. Chain drive has been discontinued. The double reduction axle has one reduction in the differential housing, which is in the center of the axle, and the other is an internal gear reduction in the wheel. The axle design is, however, different from the general internal-gear type in that the axle-drive shafts are within and concentric with the axle housing. These drive shafts are floating types, permitting of quick removal. The second reduction within the wheel hub is through a spur pinion on the drive shaft, which meshes with the second gear, which in turn meshes with an internal gear attached to the road wheel inside of the hub case. This type of construction permits of the complete axle mechanism being encased and running in oil.

The bevel drive and differential gears are carried in the ball bearings mounted on a detachable axle plate, which may be removed as a unit from the forward face of the axle, to which the plate is bolted. The axle housing affords a clearance very nearly the same as that of a straight axle design. The axle housing is a steel casting, and the unsprung weight is said to be less than that of the chain-drive type.

In addition to the new drive system, improvements and refinements have been made in a number of features of its 3 and 5-ton trucks. Among these are a unit power plant, which is an evolution of the White block engine; a cast radiator of the vertical-tube type with a removable head and a new system of brakes.

The 3 and 5-ton are identical in design, the only difference being in the size. Both use a unit power plant, comprising a four-cylinder block engine with a removable

*Plan view of the new White heavy chassis, showing the rearranged braking system*

cylinder head. In the 3-ton truck the bore is  $3\frac{3}{4}$  in., and in the 5-ton  $4\frac{1}{4}$  in. The stroke in both is  $5\frac{3}{4}$  in. The cylinders are L designs. Pressure oiling is used for the crankshaft bearings.

The radiators have cast removable heads, permitting quick replacement of damaged tubes. The radiator is flexibly mounted on springs. The clutch is a single-plate type, operating in oil. The gearset affords four speeds forward. Fuel is fed by vacuum to a White carbureter.

The service brakes operated by pedal, contracts on a drum on the drive shaft in the rear of the gearbox. It is mounted amidship on a cross-member of the frame, where it is more accessible and where a larger braking service can be used than if it were on the wheel. The emergency brakes, operated by lever, expand in drums on the rear wheels, completely inclosed and pro-

vided with a simple external easily-operated adjustment.

Metal wheels are standard equipment, and on the 3-ton truck carry 36 x 5 solids in front, and 40 x 5 dual solids, S. A. E. rear tires. The pressed-on type is standard equipment, but demountable may be obtained at extra cost. The 5-ton truck has 36 x 6 solids, in front, and 40 x 6 dual solids in the rear.

*External appearance of the new double-reduction-drive White truck*

*The mobile employment department used by the Packard Motor Car Co. to visit various districts of the city for the purpose of obtaining labor*

## A Mobile Employment Department

ONE way of meeting the labor shortage has been found by the Packard Motor Car Co. Instead of waiting for men to apply at the office of the employment department it sends out a wagon to round up the men and bring them back to the factory. This scheme has been in operation by the company for 2 months and is proving very satisfactory.

Trips by the "Employment Wagon," as it is styled at the plant, are usually made the latter part of the week. A great number of applicants appear at the office the first part of the week, making it unnecessary to send out after men, which, in fact, would not be possible, because the men who write up the applicants at the office could not be released to go with the wagon. Toward the end of the week, when fewer men apply at the office, the interviewers have little work to do, making it possible for them to take the wagon and do their work outside.

# Lack of Confidence

## *Between Employer and Employee*

### The White Plague of Labor Efficiency

Individuality of Worker Must Be Recognized—The Worker's Ability Cannot Be Computed With An Adding Machine—200 Years of War in Industry—Present Status of Belligerents

By Harry Tipper

#### Six Items From Recent Events :

- 1—"The Steel Corporation adopts 8-hour day."—Daily newspaper.
- 2—"A plank in the recently adopted platform of the Socialist Party of New York State demands a 6-hour day."—Report of Convention.
- 3—"President Wilson requests telegraph companies to waive their rights to discharge men who had joined a union."—Daily newspaper.
- 4—"The great majority of the causes of industrial unrest specified in the reports have their root in certain psychological causes. Want of confidence is a fundamental cause."—British Commission Report.
- 5—"The commissioners have been struck with the fact that employers generally appear to have taken a broad and sympathetic view of the conditions of the employees and of the need that in many respects exists for improvement in present as well as in pre-war conditions, while on the other hand the employees collectively do not offer any demands that are extravagant or incapable of being met by the friendly co-operation between employer and employee."—British Commission Report.
- 6—"On all sides it has been recognized that the closest co-operation of employer and employee is necessary if the full resources of the steel industry are to be thrown into the scale on the side of democracy."—The Iron Age.

THESE items, picked from events of recent date, indicate the nature of the warfare continually being waged between capital and labor, the interferences of Government in the matter, because of its necessities, and the hopes of progressive settlement as seen by authoritative observers.

For a century the history of the relations of employer and employee has been the history of warfare—a warfare between the more or less organized bodies of employees and the more or less organized groups of industrial employers. Year after year has witnessed the offensive and defensive measures of warfare, the losses and destruction incident to which reach appalling figures. From time to time the Government has been obliged to interfere with the interest of the general body of the people, each interference establishing new limitations and new compromises.

Perhaps this will sound far-fetched to the average

manufacturer who has no recollection of any desire—except for the peaceable continuance of his business and enjoyment of his profits.

Nevertheless these industrial relations have caused more turmoil, more legislation, loss and fundamental changes in Government than all other political exigencies combined—up to the time of the present conflict.

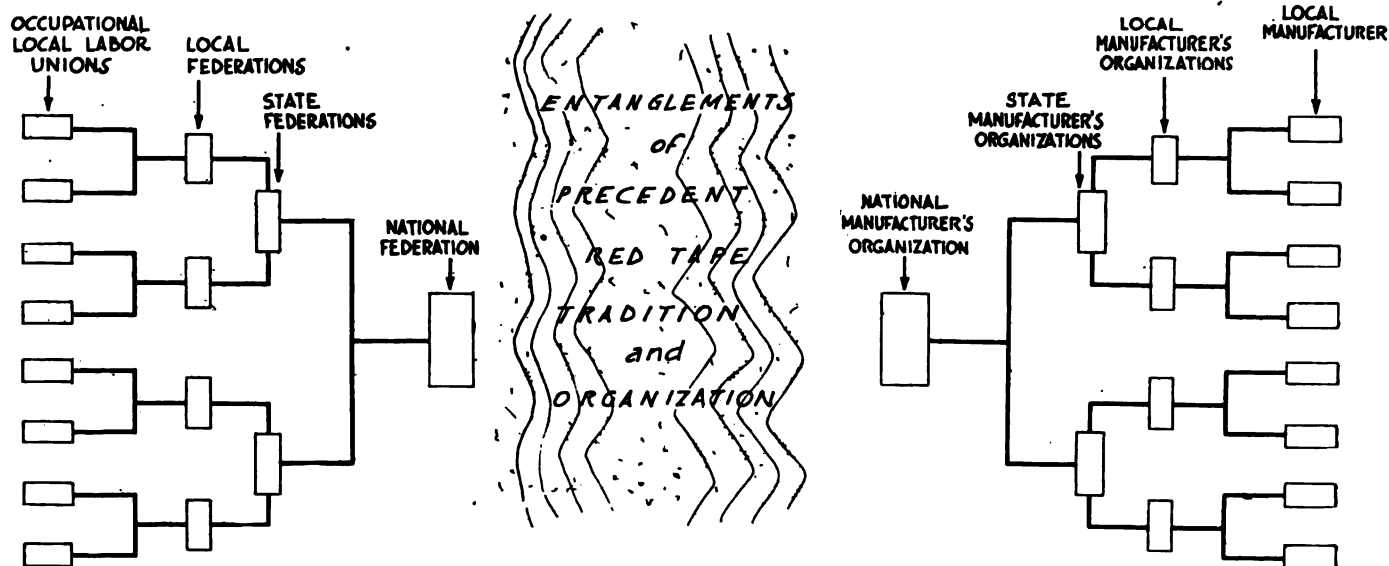

A century ago the owner's control was absolutely autocratic. The records of conditions in many of these early manufacturing establishments read like the records of the enslaved workers in German occupied areas.

The growth of labor organizations began in the revolt against such conditions and was the original reason for the bitterness of feeling among workmen against employers and the common action of employers in the defense against these attacks.

The worker contends that no amelioration of his condition had been offered to him until he has fought his

## WHICH?

## Opposing Armies of Industry—or

## Co-operative Army of Industrial Democracy

way up to it, and the history of the conflict shows that the influence of the employer has been exerted quite generally to avoid higher payment of wages, lessen the hours or alleviate the conditions of work. While his political pressure has been exerted, continually, to prevent the passage of legislation limiting his control.

The employer contends that the workers' demands are frequently unreasonable, that the owner of the business should control and that he is willing to do everything which the competitive system will allow; and there is undoubted truth in his statements. But whatever the basis of these contentions, the fact remains that this warfare has been of grave moment, its consequences far reaching and of the utmost practical importance.

Some of these consequences are:

- 1—The increasing solidarity of labor and the rapid development of a class consciousness in labor, resulting in a class distinction fostered by labor itself.
- 2—The growth and increasing combination of labor organizations so as to consolidate power.
- 3—The increasing tendency for labor to influence legislation.
- 4—The constant increase in the demands for labor.
- 5—The suspicion and prejudice against capital.
- 6—The constantly increasing Governmental interference in industrial relations and a growth in the demand for Governmental control.

- 7—The utter failure of capital to hold its original position and its constant retreat as the matter has progressed.

But the most significant result has been the constantly increasing tendency to collectivist action—matters being considered by the whole body of industry and labor and frequently Government, where these should have been settled by the co-operation of a small group of individuals.

A man was discharged for drunkenness on a railroad in Great Britain and before the question was settled it involved the employment of 350,000 men, all the railroad communications and the Government of Great Britain.

A few days ago the entire telegraph communication of the whole country was imperilled because a few men were guilty of joining a union. The result has been Governmental control.

This collectivist action, in its neglect of the individual and constant increase of bureaucratic precedent, takes no account of the triviality of the case or the lack of reason for putting in motion the ponderous machinery of its warfare.

For the German, the Savajero incident was enough to start the whole nation to a complete interruption of the world's usual course, and for the Bolsheviks the name "bourgeoisie" is enough to cause a killing.

## Our Industrial Movement

The important thing in the world just now is not just where we are, but in what direction are we moving?

All warfare is destructive, and this industrial warfare, carried to its logical conclusion, will destroy the basis of co-operative individualism upon which our political system is laid and upon which the industrial future must be founded. We need industrial peace in order to work out the opportunities and possibilities that lie before us. This peace requires construction, co-operation, not conflict; individual attention and action, not legislative attention and interference.

The present time is opportune for considering these constructive measures. The great war has swept away precedents, enlarged many problems and created new ones, reconstructed ideals and created in man's mind the desire for betterment, the willingness to reconstruct,

*De Haviland 5A single-seater fighter*

## De Haviland Single-Seater Scout

Equipped with Rotary Le Rhone Engine—Upper Planes Staggered Backward—  
Plywood Used in Fuselage Construction

**D**URING the summer of 1917 the British made use on the western front of a De Haviland tractor scout, the first models of which bore the number 5, and later ones, 5A. This machine was fitted with a 110-120-hp. Le Rhone rotary engine. The armament consisted of one Vickers machine gun, operated through the intermediary of a Constantinesco interrupter gear, for which 750 rounds of ammunition were carried.

This De Haviland scout has a total weight of 1250 lb. Its performance, according to the British official rating, is as follows: Endurance at 10,000 ft., including climb, 3 hr.; ceiling, 16,000 ft.; speed at ground level, 109 m.p.h.; speed at 10,000 ft., 102 m.p.h.; climb to 10,000 ft., 12 min. 4 sec. The machine has a span of 25 ft. 8 in., an overall length of 22 ft. and a height of 9 ft.

A brief technical description of the De Haviland 5 appeared in a recent issue of a German aircraft periodical and thence found its way into the British aircraft press. The particular machine described was manufactured by the Darracq Motor Co. in London and bore the distinguishing mark A9435.

The machine is a single pair-strutted biplane, the upper planes having a reverse or backward stagger of  $27\frac{1}{2}$  in. Both planes have a span of 25 ft.  $8\frac{1}{2}$  in. and a chord of 54 in. The upper planes are secured to a center section and the lower ones to wing roots on a level with the lower longerons of the fuselage. A dihedral angle of 172 deg. is formed by the wings, which have no sweep-back. Near the center section the angle of incidence of the upper plane is 2 deg.; near the tips,  $2\frac{1}{2}$  deg., while the lower planes have a uniform angle of incidence of  $2\frac{1}{2}$  deg.

Spruce spars of I section are used. The ribs are spaced from 11 to  $13\frac{3}{4}$  in. Between each pair of adjacent ribs are placed two auxiliary ribs extending from the leading edge to the main spar.

Flying and landing cables are made of profile wire in single arrangement. Ailerons are attached to all four planes at the rear spar. Their control wires run outside the planes, below in front of the leading edge, above over the front spar. The corresponding ailerons are connected by profile wires. The conventional wire-braced wood-framed fuselage, with four longerons, is strengthened in front, to a point behind the pilot's seat, and behind below the fixed tail-plane, by planking of plywood of  $\frac{1}{8}$  in. thickness.

By the mounting of fairings, the front part of the body is given an almost circular shape. The fuselage is covered with canvas. The solid wooden non-covered landing gear struts are of streamline section. The through running axle rests between two auxiliary streamlined covered ones. There is no limit to the range of spring action. The one-piece tail-plane is secured to the stern end of the body, with an angle of incidence of 1 deg., and is without the arrangement for changing the angle of incidence, which has so far been generally used. Each part of the divided elevator is provided with levers with single control cables.

The engine is a 110-hp. Le Rhone rotary, which has given 130 hp. by earlier tests. The main fuel tank, with a capacity of  $26\frac{1}{2}$  U. S. gal., and the oil tank, with a capacity of  $5\frac{1}{2}$  gal., are mounted behind the pilot's seat. In addition, a gravity tank of 7 gal. capacity is placed on the right upper plane. Fuel is fed from the main tank by compressed air, which is obtained from a small propeller-driven air-pump, fixed to the left landing gear strut. The fuel supply suffices for a flight of about 2 hours' duration.

In the pilot's seat are arranged the instruments. To the right of the pilot there are two gasoline tubes with stop cocks; there is also an arrangement for a spring relief of the elevator management. In the middle are

found a tachometer, speedometer, altimeter, contact-breaker, watch and compass. To the left there are the gasoline and charge control levers, and the control of the hand air-pump.

Two other airplanes of the same type, which were manufactured by the Aircraft Mfg. Co., Ltd., London, show a considerably more convenient arrangement of the instruments, and are also provided with electric lights for night flying.

The machine is armed with a fixed machine-gun of the Maxim type, mounted on top of the cockpit to the left of the pilot's seat. Hydraulic control is used, and release is by means of a Bowden wire. From remains found in the fuselage it was ascertained that the cartridge belt was a metallic one. The belt-box lies below the machine-gun, directly behind the motor.

The weight of the airplane empty was 1015 lb. The weight of the fuel, if the tanks are filled, amounts to 237 lb., so that the total weight without passenger is about 1250 lb.

This machine became obsolete in October, 1917.

### Details of landing gear

## Lack of Confidence Between Employer and Employee

(Continued from page 626)

which makes it possible to progress without the usual resistance.

But this constructive program must be based upon a study of human necessities and requirements at least as adequate and patient as the study which we have given to the mechanical side of industry. It must begin with the individual—not as a unit. There is no such thing as a human unit, but the individual, different from all other people in some respects. We must recognize the statement of the philosopher:

"The teachers and leaders, whose voices are presently drowning better counsel, are assuming in all their proposals that there exists such a substantial uniformity among men that a counting machine can rightly evaluate policies and destinies. In their meager imagination, uniformity seems a lovely thing, whereas it would be the night in which all cows are black. Nature, life, will not allow uniformity. It insists on differences."

The greatest concern of the individual is the status of himself as an individual, the welfare of his family and the condition of his community.

## Recognition of the Individual

Those things are so definitely the major part of his consideration that it is only in times of great national necessity that the interests of the ordinary individual extend beyond his community. The closest concern of the individual worker lies in his recognition as an individual and his recognition as a responsible part of the organization. All general questions of labor organization, capitalistic groups, governmental control, are far away from him. They obtain their strength because, lacking individual recognition, these large, impersonal matters are offered to him as a panacea by which he can obtain the rest of the items close to his concerns.

In a corner of New England there are two mills of about the same size and not many miles apart:

Mill A pays higher wages, has better physical conditions and more material advantages, yet its record of 10 years is one of a series of labor troubles from beginning to end. Its labor turnover is three or four times as high as its neighboring mill.

Mill B has never had a serious labor disturbance. I asked the general agent of these mills why. He said: "Mill A manager is a keen business man, but he has no human sympathy and understanding. Mill B manager knows each worker by name and something of their history—he understands them and they believe in him."

Then I asked which is the most profitable. Immediately came the answer, "Mill B."

The British Commission's statement is significant:  
 "Want of confidence is a fundamental cause.

"The board of directors and officers of the Midvale Steel & Ordnance Co., Cambria Steel Co. and subsidiary companies, recognizing the fact that the prosperity of the companies is inseparably bound up with the general welfare of its employees—"

It is around the council tables of the individual organization that executives and employees of that organization—with full knowledge of its local and immediate necessities—can settle the questions contingent upon this co-operation, and not through large impersonal bodies of labor unions and industrial groups.

In individual cases this has been done, successfully, for years—despite general tendencies to the contrary, and it can be done by others. Labor turnover, production, efficiency and industrial stability depend upon the settlement of these questions for each individual concern and they need that individual study and attention.

## Method of Treating Positive Electrodes

**A** NEW method of treating the positive electrodes of primary batteries, with a view to introducing metallic oxides as depolarizers, has been invented in France, says *The Engineer*. The electrode consists of a shallow plate of copper or iron presenting numerous conical points to the alkaline element in the cell. The edges of the plate are bent so that it becomes a form of shallow box into which the depolarizing oxide is introduced. This material is mixed in a powdered state with a suitable alkaline hydrate or alkaline earth, and introduced into the interior of the box formed by the positive and a zinc plate as negative. The whole is sealed with rubber, a small vent being inserted to allow for the escape of gases, and cased in metal stiffening bands.

# High Ideals Pursued in Craig Tractor

Leather Boots, Anti-Friction Bearings and Oil-Less Bushings Used Liberally—  
Engine Lubrication Force Feed and Lubricating Oil Cooled in  
Radiator—A Universally Adjustable, Comfortable Seat

By P. M. Heldt

**A** YEAR or so ago one of our largest industrial organizations delegated a number of Cleveland men to make a canvass of the tractor field to determine the prospects for a high-grade tractor transmission which the concern referred to was developing. The result of their investigation led these men not only to make a most enthusiastic report regarding the transmission proposition, but to organize among themselves a company for the production—on an assembling basis—of a tractor, which, though comparatively high in first cost, should appeal to the farmer on account of its staunch and well-thought-out design and its consequent reliability and low up-keep cost. The Craig Tractor Co. of Cleveland, to which reference is made, is not yet in regular production, but a factory has been completed for it at Bliss Road, Cleveland, the design of the tractor has been finished and the components have been selected and condition contracts for them let.

The Craig is a three-plow tractor with a 15-25-hp. rating. This rating in itself points to high efficiency. The usual proportion of belt to drawbar power being 12-25, thus showing that the amount of power required to propel the tractor itself is low in the Craig. Another interesting feature of the machine is that it is of the frameless or backbone type, the engine and transmission housings forming a structure connecting the front and rear axles. This, in part, accounts for the moderate weight of the tractor—4500 lbs.—which, of course, has a bearing on the efficiency.

The engine is of Beaver manufacture, but departs somewhat from the standard Beaver design. It is of 4½-in. bore and 6-in. stroke and is governed to run at 950 r.p.m. Features which have been changed at the instance of the Craig designers include the crankcase, oil pan and bell housing. The crankshaft is of the three-bearing type, the bearing sizes (front to rear) being

2⅜ x 2¾ in. These dimensions show that the crankshaft is very rugged and has very substantial bearings, which in conjunction with the forced lubrication, to be referred to later, should exclude all danger of hot bearings. The size of the engine, i.e., the piston displacement, is considerably above the average for a three-plow tractor, but the designer of the Craig, John Dietrich, who has had considerable motor truck experience, holds the view that the reason why there has been so much trouble with tractor engines in the past, as compared with truck engines, is that the former have been made to operate too near their limit.

Cylinders are cast in a block, and the valves are located in the detachable heads and are protected by two cast-iron cover plates. A copper-asbestos gasket is placed between the cylinder block and cylinder head casting. The valves are 2 3/16 in. in diameter at the throat and have a lift of ⅜ in. The cylinders are offset ½ in. relative to the crank axis, a feature which is of particular advantage in a low-speed engine. The piston pins are clamped in the connecting rods and rock in Non-Gran bushings in the piston bosses. Four bolts are used to hold the caps to the connecting rods. The rods are 12½ in. long or more than twice the length of the stroke.

While the waterjackets extend far down the cylinders, considerably beyond the lower end of the stroke, they do not extend quite to the cylinder flange.

Coming now to the crankcase, this, of course, is an iron casting, with a separate cast oil well bolted on below. There are small hand holes in the crankcase proper,

*The Craig is a three-plow tractor rated at 15-25 hp., the total weight being 4500 lb.*

*Front and rear views of the Craig tractor, showing the similarity to standard automobile practice in the use of springs, steering knuckles and rear axle. The gearset is a Nuttall*

but in the Craig engine there are, in addition, two 11 x 14 hand holes on each side of the oil well or base, through which the crank pin and main bearings can be adjusted. The camshaft is of the type with enlarged bearing journals, which can be withdrawn complete from the crankcase at one end. Its bearing dimensions (front to rear) are as follows:  $1\frac{3}{4} \times 3$  in.,  $2\frac{1}{2} \times 3\frac{1}{8}$  in.,  $2 \times 2\frac{5}{16}$  in. The camshaft proper is  $1\frac{1}{4}$  in. in diameter. The gears for driving the camshaft and accessories shaft are cut with helical teeth. The camshaft gear meshes directly with the crankshaft pinion and in turn drives a third shaft from which the fan, water pump and magneto derive their motion. This latter shaft, of course, revolves at crankshaft speed.

A bell housing is cast integral with the crankcase at the rear, and this conforms to the S. A. E. standard except that  $\frac{1}{2}$ -in. cap screws are used instead of  $\frac{3}{8}$ -in. There are four supporting arms cast on the crankcase, two at the forward end and two on the bell housing, and two pressed steel channels are bolted to these arms, the channels extending some distance forward of the engine, where they have a drop-type pressed steel cross member riveted to them.

Kerosene is the fuel used in normal operation, and a fuel tank with capacity for 25 gal. kerosene and  $3\frac{1}{2}$  gal. gasoline sets on top of the bell housing, which is made flat on top for the purpose. In fact, the arrangement of the fuel tank on top of the bell housing, the manner of holding it in position by fabric-lined steel bands and the method of bolting the steering gear housing over one core hole in the bell housing and closing the opposite one with a plate on which are cast instructions regarding clutch adjustment and shifting collar lubrication, form together one of the cleverest features of the whole design. The top of the fuel tank conforms to the top of the radiator and has a hood ledge secured to it. The tank is made of No. 16 gage terne plate, double lap seamed. At the bottom of the tank in an accessible position to one side is a three-way valve with strainer and drain. In the central position all fuel is shut off from the carbureter; in one extreme position gasoline is fed, and in the other, kerosene. The radiator is fitted with a motometer, and this indicates to the operator when it is time to change over from gasoline to kerosene.

A Stromberg  $1\frac{1}{2}$ -in. carbureter is used and a special design of combined inlet and exhaust manifold which differs from that shown in the photographs. In this the exhaust passage surrounds not only the horizontal portions of the inlet manifold, but the vertical part as well, coming right down to the flanged carbureter joint and then turning backwards at an angle. The single throttle valve in the inlet passage is acted on by both the governor and the hand throttle lever. The former is the Pharo hydraulic type, mounted in front of the engine. It is completely enclosed, yet adjustments to obtain changes in governing speed are easily made. The throttle lever is of very substantial design, with a fish-tail grip and mounted on a side-ratchet sector on the steering bracket. Ignition is by a Berling magneto with impulse starter. The spark plugs are located in the cylinder heads on the opposite side from the magneto, and the ignition cables are carried across the cylinder heads between the two valve covers through a Y-shaped cast cable tube, making a neat construction. What is known as fixed-spark ignition is used.

Oiling is by a combined force and splash system. A

*Type of steering gear used on the Craig tractor*

*Arrangement of steering gear, controls and operator's seat on the Craig tractor*

gear pump at the bottom of the crankcase forces oil under a pressure of about 30 lb. per sq. in. to all main bearings and through the drilled crankshaft to the crank-pin bearings. Two gage cocks on the oil well serve to determine how the oil level in the well stands with relation to the high and low limits, and a pressure gage mounted in direct view of the operator indicates the oil feed pressure. The cylinder walls, piston pin bearings, camshaft bearings and cam followers (the latter of the roller type) are lubricated by the spray thrown off by the revolving crankshaft and by the splash from sheet metal troughs under each connecting-rod head.

A highly interesting feature of the oiling system is the provision made for keeping down the temperature of the oil. A part of the radiator, about 3 in. in width, on one side, is partitioned off and is connected in the oil circulating line. From the delivery outlet of the pump the oil is forced through a neatly arranged pipe to the top of the oil cooler and from the bottom of the oil cooler it is led to the main distributing pipe, which is cast in the engine crankcase. The engine is provided with a breather similar to that used on the Liberty truck engines, which comprises a poppet valve which opens to let excess air out of the crankcase but closes when there is suction in the case. Mention may also be made in this connection of the Breese petcocks for the cylinders, which are provided with spring covers. The ordinary petcock on a tractor engine always fills up with dust and grit, which is washed down into the cylinders every time the engine is primed.

Lubrication of the valve rockers on top of the engine is effected by means of two good sized oil cups which require filling once every day or every other day. It was first planned to carry an oil lead from the main lubricating system to the valve housings, but as this would have involved outside piping and the breaking of joints every time it was necessary to get at the valves, the present system was considered preferable. A horizontal pipe

extends through each of the two valve housings with an outlet over each valve rocker bearing, the rocker hub being formed with an oil pocket containing a felt pad. The oil cups are screwed to the outer ends of these distributing pipes.

There are also a number of original features in the cooling system. The water spaces around the combustion chamber are very liberal, and water is carried all around the spark plug bosses and extension glands. The rubber hose used between the radiator inlet and pump outlet is of a special type. It is inlaid with half-round wire and there is no fabric inside the wire, hence there is no possibility of the rubber perishing and the fabric coming loose and choking up the pipe. Moreover, the hose is capped, that is, the fabric does not come through to the ends, which does away with fringing and consequent deterioration.

With the flat side of the half-round wire toward the inside, the inner wall of the hose is very smooth, insuring the most rapid circulation. The fittings for the return of the water from the engine to the radiator are so designed that only a short length of hose is required, and this does not need to be bent in any way. Circulation is effected by means of a centrifugal pump already referred to. The radiator is a Modine with removable core and sets on brackets riveted to the front pressed steel cross member. Its top and bottom tanks and side supports are formed in a single casting. About 7 in. back of the radiator sets the 20-in. fan with four curved blades riveted to a 3/16-in. steel spider. The arms of the spider are of considerable length and support the blades rigidly, thus minimizing the warping of the blades with each change in speed, which is often the cause of breakage of the spider in large fans. Drive of the fan is through a 1 5/8-in. belt at twice crankshaft speed. Belt adjustment can be made by means of an eccentric fan bearing housing. A length of pipe is screwed into this housing radially and serves to carry the oiler and also

for turning the housing by tightening the belt. To prevent grass, etc., being drawn into the radiator and choking up its air passages, a screen is mounted in front of it. All radiator fittings are flanged fittings.

There are core holes in the cylinder head casting at both ends, and the plates closing these openings are formed with hooks by which the cylinder head can be lifted off. The part bolted over the forward hole is, however, not a simple plate, but the water outlet fitting. The cylinder head is very rigidly held in place by means of 19 studs. Complete, the engine weighs 1050 lb.

The clutch is the Twin Disc, which was selected by reason of its easy adjustment without the use of tools, and its smooth action. It is operated by means of a hand lever and is positively opened and closed, having no spring return. We expect to describe this clutch and illustrate it in a forthcoming issue.

The transmission is the new Nuttall described in AUTOMOTIVE INDUSTRIES for September 19, of the type combining the transmission proper with the rear axle. The only important change from the Nuttall standard design is that the bell housing extension is left off to shorten up the machine. Two 1-in. bars extend from lugs on the bottom of the engine bell housing to corresponding lugs on the transmission case. They serve to stiffen the backbone or frame construction and also as guides when sliding the transmission back if it is desired to remove the clutch or in dis-assembling the power plant. The belt pulley is 11 x 7½ in., and the belt speed at 950 engine r.p.m. figures out to 2700 ft. per minute. The weight of the transmission with axle is 1385 lb.

A standard Gemmer worm and wheel type steering gear is used, the regular 2-ton truck model. It gives a reduction of 8.5:1 in the gears, and a total reduction of about 11:1 is obtained through levers and gears combined. Steering is effected through a 20-in. cast iron steering wheel, the rim of which has an inverted V section. As already stated, the steering gear housing is bolted to the side of the engine bell housing, and the upper end of the rearwardly inclined steering post or shaft has a bearing in a combination bracket bolted to the transmission housing where the control plate was intended to go. This bracket carries the throttle lever and gear control lever in addition to the steering post. There are two universal joints incorporated in the steering post or shaft, of the ball type as used on machine tools, as there is no means of holding the lower and upper steering post bearings in rigid alignment. These joints are inclosed in leather boots held in place by buckled leather straps.

There is a sheet steel hood over the top of the engine extending from a ledge on the fuel tank to a ledge on the radiator, and being held in position by means of four bolts passing through hood and ledge, two at each end. The sides of the engine space are normally open, so that the air can circulate freely all around the engine, helping to cool the engine and immediately carry off all dead gases. However, to protect the engine against the weather, especially when the tractor is standing in the field for extended periods, heavy tarpaulin curtains are provided on both sides of the hood. These are ordinarily rolled up and held up by three straps. In deciding upon the use of this type of engine enclosure, in preference to the removable type of hinged sheet metal hood used on passenger cars and trucks, the designer was motivated by the consideration that the farmer is apt to let loose sheet metal parts lay in the field in rain and shine, so that they soon take on a coating of rust and the machine begins to look shabby.

A special design of cast seat is furnished. It is somewhat similar to the standard implement seat, but is

deeper, so that you sit in it instead of on it. The seat is supported on a flat spring of vanadium steel and there is an auxiliary spring below it to take the shock when the tractor wheels drop into holes. This permits of making the main spring light and flexible without danger of its breaking at the base when the machine receives a severe jolt. The seat support is quite a mechanism, and it is evident that the designer has had an eye toward the comfort of the operator. In the first place, the seat can be adjusted fore and aft to suit operators of different stature. Then the seat can be swung around a vertical axis, either one-eighth or one-quarter turn, to enable the driver to readily mount and dismount. Finally, there is an adjustment around a horizontal axis so the driver may sit straight up whether the tractor is running with one wheel in the furrow or on level soil. The two last-mentioned adjustments can be made without the use of a wrench, the seat being held in position by means of heavy springs and locking dogs engaging into notches.

The front axle is an I-section drop forging, and is identical with a standard size truck axle, except that it is provided with brackets for a half-elliptic cross-spring and with bosses for radius rods. The cross spring is of vanadium steel, provided with self-lubricating bushings and shackled at both ends. To the middle of the spring is clipped a swivel pad which has a pivot joint with the front drop bar of the engine. A universal joint of the ball type is incorporated in each radius rod near the rear end, which end is fastened into a lug on the bell housing. A leather boot protects this universal. It will readily be seen that with this construction a very flexible running gear is obtained. The tie rod is back of the axle in a protected position, but the steering gear and the drag link, with its joints, are exceptionally accessible. The front wheels are 32 x 6 in., and, owing to the narrowness and height of the engine frame, the tractor can be turned in the relatively small circle of 17 ft. radius.

P-T pad wheels are fitted at the rear, 44 x 12 in., with 2-in. cleats on each pad. Two pads are always in contact with the ground. The pads can quickly be replaced with wider ones (special) for use on soggy ground. Fenders of No. 16-gage stock, stiffened by angle iron, extend practically halfway around the wheels, and dust guards come down on the inside of the wheels to the axle housing. These fenders are built up, and no spot welding is used in their manufacture.

To a web at the bottom of the transmission housing is connected the drawbar. It has a spring behind it to absorb shocks, and is swiveled around a horizontal axis so that the height of the hitch can be varied by raising or lowering the rear end by means of a link depending from a bracket bolted to the upper part of the transmission housing. Thus the height of the hitch can be varied between 12 and 18 in. At the end of the drawbar is a horizontal crossbar with a number of holes in it, which gives a range of 6 in. for sideways adjustment of the hitch. There is a clearance of 16 in. at the bell housing and 10½ in. at the rear housing.

The exhaust pipe from the engine is carried to the rear of the tractor and the exhaust gases are discharged in such a way that the driver will not be annoyed by them. However, for certain kinds of work, such as hauling a binder, hay loader, etc., the low rear exhaust involves some fire danger, and for such use the company will furnish, at an extra cost, a special exhaust pipe which carries the exhaust gas straight up 3 ft.

The Craig tractor has an 88-in. wheelbase and a 52-in. tread, figured to the outside of the front and the center of the rear wheels.

# Analysis of Automobile Merchandising in New Zealand

## PART II

### Service Was Started with American Car Sales—Good System of Macadam Roads Linking Cities—Possibilities of Truck Sales—Leading Industries

By G. A. Worrall\*

**T**HE closing paragraph of last week's article on New Zealand told how good roads have been a potent factor in the heavy sale of American automobiles in New Zealand during the last 3 years, how practically all cities of 5000 population are linked together by a system of metal and macadam roads.

Once off this system of metalled roads the automobilist finds himself on dirt roads of all kinds. The nature of these dirt roads is best evidenced by the fact that the government has seen fit to place automobile springs on the free list. There is no local spring making industry worth while and a good quota of repair springs is needed in all parts of the two islands. The roads are also particularly hard on axles and steering parts, all of which have to be liberally stocked in the stores of the dealers.

All seasons of the year are suitable for the automobile in New Zealand. Being south of the equator, the seasons are opposite to those in America. The summer selling season begins in November and continues until April. These months constitute the dry season. The months from April to the end of October can rightfully be classed as a wet season. These wet months are accompanied by high winds. New Zealand is located in what is known as the "roaring forties." There are times when motor cars have been carried off mountain roads by the winds. It is not unusual to see signs along the mountain roads and passes advising the tourist to be-

ware of the winds. There are cases on record of where the top has been carried off a car and has been found over 50 miles distant.

The motor truck business in New Zealand has just been touched. It is here and awaits the hand of the manufacturers and dealers who are ready to take up the development of it. The great possible truck selling field is that of what is known as the "country carrier." He would be called a drayage man in America. His main job is to transport the 100,000 tons of wool from the country districts to the cities. This means a haul of from 5 to 50 miles. Generally 5-ton trucks are best suited for this work. Few of the large station owners or sheep raisers own their own trucks, they preferring to turn the wool transportation over to these large country carriers. Practically 95 per cent of these country carriers use horses. They know of the motor truck, and if they can be financed they are very good prospects for the motor truck.

There is a good opportunity of truck sales in the road building field, which generally calls for a 5-ton truck with power dumps. These trucks are purchased by borough and county councils.

Fewer trucks are used by the carriers or drayage firms in the city than the country carrier. The cities are not manufacturing places and the main use of the truck is to transport raw products to the wharves and transport the imported wares to the warehouses.

The cities offer the same field for a variety of sizes of motor trucks and deliveries that cities of similar sizes

\*Mr. Worrall spent 11 months in New Zealand as special representative of the foreign department of the White Co. He traveled on both islands and studied conditions for automobiles and trucks.

The village Stratford in Taranaki Province, New Zealand, which is typical of many selling places in that country. This shows the main street of the village, in which are located three garages. Stratford is in the heart of a dairy country and one in which some wool is produced

in America do. Store delivery and other problems are generally met with.

The advent of the American automobile in New Zealand started the movement of service necessary for the good of the industry. Previous to the war the European manufacturers had given little thought to service, which was largely due to the fact that importers in New Zealand who handled a wide line of merchandise classed automobiles as one line of merchandise. These importers were not familiar with service. It was entirely foreign to them, and it was not until the American manufacturer began selling in quantities that service became a tangible factor in New Zealand.

Of signs of service prior to the war there seemed to be none, and when cars were in need of spares it required from 3 to 6 months to have them forwarded from England. Passenger cars were not very numerous and trucks could be counted. Oversea manufacturers did not insist upon a stock of spare parts, and their importance was not really recognized because of the limited number of buyers and the representations being in the hands of large importing houses who either bought the machine outright and sold it for a profit or ordered it on a commission basis. At least their profit marked the end of their interest.

This practice has brought a great many high-grade motor vehicles into ill repute and has been no little source of annoyance to the reputable manufacturer.

With the flood of American motor vehicles manufacturers in some cases have sent out a representative to co-operate with the agent. In all cases good resulted. The agents have progressed along American lines, stocking in large amounts of spare parts, as is the case with the Ford, Dodge, Chevrolet, Overland, Republic and White trucks.

While many manufacturers have secured representation through commission houses, and are now making ready and secured sales, they must not expect to hold this trade after peace is established, but those who are now organizing and have caused large investments in spare parts and are insuring the owners of their products, their satisfactory performance will necessarily be more than on an even basis to hold their own.

The word service as applied to foreign trade does not mean to simply have spare parts on hand, but there should be a personal touch between the manufacturer and

the owner. This is particularly true of the truck business; a live, obliging factory representative's visit to an owner will please and flatter him. From many of these weather-beaten owners invaluable material may be obtained to hold the market successfully. A local agent in good standing paying a client a visit in company with a direct factory representative goes a long way toward securing a repeat order, but the agent should be the salesman and the factory representative an adviser.

It is regrettable that the large and powerful independent houses have secured valuable agencies and right from motor makers. It is not advisable to grant any of these houses selling rights, as they are not equipped to back up their sale and sooner or later the products come to grief because of inexperience, lack of attention to the purchasers, lack of spare parts and an absolute indifference on the part of the selling firm unless additional profits are involved. Thus, in the end, the manufacturer's good name suffers, which is exceedingly difficult to regain no matter how meritorious the product.

At present mechanics are very scarce throughout New Zealand, the best men having gone to the war. In peace times mechanics are scarce, as New Zealand is agricultural rather than inclined to manufacture, making it necessary to train all mechanics. Wages for mechanics are high and repair rates approximately \$1.25 per hour for work. All labor is in the hands of unions. Repair jobs are generally very slow in coming through.

To-day motor trucks in operation in New Zealand do not equal 3 per cent of the horse vehicles in use. Some enterprising firms, such as the New Zealand Express Co., are using trucks on their long hauls. The truck situation relative to the horse has not been studied sufficiently to make the motor vehicle popular.

In the largest cities, motor trucks will not pay on the short haul to the wharfs, where they must wait in line for hours before discharging their load. Most of the port cities are extremely hilly, with very little width, but running miles along the harbor edge. Along the length of these cities where a run of several miles is necessary to deliver a load the truck pays well, but for delivery to the residential sections, the all-around truck has not yet been demonstrated consistently. The ideal should be light, with plenty of power.

(To be continued)

Newton King, garage in Stratford, New Zealand, a town of three thousand population, is represented of the best type of garage in such a city. King represents the last of a type of merchant importers of New Zealand who have handled automobiles. He was formerly a wool auctioneer, after which he entered the farm machinery and grain field and six or seven years ago took up the automobile business. He has a chain of garages and salesrooms in seven or eight towns of Taranaki. He handles Studebaker, Hudson and White

Throughout New Zealand fairs are held in November, which is not the fall month but the opening spring month in New Zealand. This is at the start of the automobile selling season. It is a good selling period for motor trucks, as the wool crop has just been sold at this time. This fair was held in Hastings and similar fairs are held in every small town in New Zealand. While different kinds of farm machinery, etc., are shown at these fairs, the automobile has been the dominant factor. Each agency exhibits its cars in its own tent

## An Outdoor Motor Car Show in New Zealand

## Types of New Zealand Salesrooms in Smaller Cities

*This garage in the town of Hastings, population 6000, is typical of the average garage and represents the new type of building that has sprung up all through New Zealand as the result of the increased sale of American cars during the last few years. This agency handles Dodge, Saxon and Hupmobiles*

*This is another new garage built in Hastings but is slightly above the average. Studebaker, Packard, Romer and Scripps-Booth are sold. Hastings is in the Hawkes Bay section of New Zealand and in it is the City of Napier, approximately the same size as Hastings*

*This garage in Wellington, New Zealand, is typical of a kind being built as the result of the increased sale of American cars and the adoption of American service and selling methods*

*This is the average garage of a sub-agent who may sell a dozen cars in a year. He has a small garage combined with a workshop which represents the entire business of the owner*

*This is an average garage in a city of ten thousand population located in a fertile wool area but with little dairy production. There are eight garages of this type in this city. Each has a good repairshop, with lathe, drill press and shaper, and some of them have battery departments*

*This garage in Hastings, New Zealand, is typical of many seen in a city of six thousand population. It affords not only garage space but repair facilities, and is fitted with the usual line of lathe machinery needed for making pretty careful repairs on various makes of cars*

## HORSELESS AGE SUBSCRIBERS

Subscriptions for the Horseless Age transferred to the subscription list of AUTOMOTIVE INDUSTRIES in the merging of the two publications will be completed in full by the weekly issues of AUTOMOTIVE INDUSTRIES to the dates of expiration shown on the records of the Horseless Age Co.

Owned by United Publishers Corporation, Address 243 West 39th St., New York; H. M. Swetland, President; Charles G. Phillips, Vice-President; W. H. Taylor, Treasurer; A. C. Pearson, Secretary.

Entered as second-class matter Jan. 2, 1903, at the post-office at New York, New York, under the Act of March 3, 1879.

Member of the Audit Bureau of Circulations.

Automotive Industries—The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repair man (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907.

## Quality in Tractor Construction

AGRICULTURAL machinery in the past has been mainly cheaply constructed machinery, judged by present-day standards in the automobile and similar lines. Not as much attention has been paid to eliminating friction and conserving power and to insuring long life of the machines as would seem desirable.

There was, of course, one very good reason why no more capital than absolutely necessary should be spent on such machines as self-binders. These are used perhaps six days, and at most twice that length of time, in a whole year. Consequently, the capital tied up in them is largely dead capital. During the six or twelve days of its actual use the machine has to earn interest for a whole year on the capital invested in it, and in order to keep down this interest charge the manufacturing cost must be kept down.

The same applies to a great many other farm tools, such as seeders, hay loaders, corn planters, corn

harvesters, etc. Each is used only during a short season, and during the rest of the year it stands idle in the shed—or in the field.

A tractor, in this respect, is in a different class. While the chief use of the tractor on the farm is in plowing, it has many other uses, such as harrowing, disking, seeding, hay loading, harvesting, threshing, filling the silo, etc. It is, in fact, a machine for which work may be found nearly all the year around. Hence the tractor should be designed for greater efficiency and durability than is usually aimed at in agricultural implements.

If power is wasted in it due to poor design, this waste goes on practically all the year; and if it lacks durability due to improper protection of working parts, inadequacy of bearing surfaces, poor lubricating devices, or insufficient strength in vital parts, its usefulness will soon be at an end owing to the more or less continuous use.

Some of the manufacturers of tractors do not seem as yet to fully realize this condition of things, but it is bound to be brought to their attention sooner or later.

No frills are wanted in tractors, and not a cent should be spent on features that are merely matters of appearance or designers' hobbies. But those things which affect the working efficiency, the reliability and durability of the machine must not be slighted.

## Why Truck Curtailment?

WHEN transportation is the greatest need of the nation it seems rather unusual to start up a program of curtailing it. The motor truck was declared a 100 per cent essential, and yet we are given a 25 per cent reduction. This seems inconsistent. These are not days to curtail the greatest essential of the nation, namely, transportation.

It seems that no definite program on a specific cut in truck production should be made, but rather that truck production should be classed with railroad rolling stock and steamboat production and given steel up to the last limit of possibility. Wherever there is a steel surplus it should go to the truck industry, rather than saying that trucks must cut 25 per cent irrespective of the steel situation.

It is further unfortunate that after the War Industries Board has made a ruling on permissible truck production that there should remain open channels of appeal by which varying degrees of extension are allowed in accordance with the determination of the protest made. If a 25 per cent reduction is just, then that should be final. If, however, it is possible to get 50 per cent increases on this 25 per cent scale, then why the use of the 25 per cent ruling at all? Why should it be necessary to make a ruling and then immediately provide means for changing it according to representations that may be made for such changes?

The motor truck is a 100 per cent national necessity, and it should be handled as such. There should be no 25 per cent reduction. Take another

aspect of the unfairness of this ruling. Firms that are filled up on war orders which they did their best to secure, and which are not manufacturing for commercial uses, are operating at capacity, and those who are not fortunate enough to get war orders are not given a chance to take full advantage of the commercial field, but have to face a 25 per cent curtailment on a 100 per cent essential. You cannot

have all war work and commercial work, too; and you cannot go entirely on commercial work and war work also; but there is no reason why the commercial end should not be given all the steel available rather than being cut to a certain level and then left to go to the trouble of getting the limit raised, providing strong enough representations can be made to secure such.

## Advertised Tractor Performances

**T**HE very general adoption of the farm tractor east of the Mississippi, where it meets with varied geographical and topographical conditions, as in Pennsylvania, New York, New Jersey, Maryland and in the agricultural states, suggests the necessity of a more rational rating of tractor speeds, capacity for plowing per day, and fuel consumption per acre than has been given out by most manufacturers.

The advertised figures of tractor performances have generally been based on performances on the large farms of the Mississippi Valley, where tractors plow furrows from  $\frac{1}{2}$  to 1 mile in length, where the ground is level and where there is not a stone to be encountered.

When a tractor company endeavors to apply figures of tractor speed, tractor plowing capacity, and fuel consumption per acre made under these Mississippi Valley conditions to the farms of Pennsylvania and New York State it is generally giving to the farmer a set of figures which it is impossible to live up to under very many conditions. When the tractor has to operate on the rolling land of Pennsylvania and do its work in fields ranging from 8 to 40 acres in extent the advertised speed of the tractor is in some cases cut in half and the plowing capacity per day correspondingly reduced. If conditions are less favorable and stones are encountered the fuel consumption rises.

During the past summer the numerous tractor demonstrations in several of the Eastern States have failed because dealers and distributors have held out misleading figures on these vital points of tractor performance. The situation is such that many farmers to-day do not believe them, and their opinions of the tractor dealer, distributor and sometimes the tractor manufacturer are impaired because of the figures on performance and fuel consumption.

It is unwise to give out many of the figures showing tractor performances that have been used this year. They work to the detriment of tractor introduction. The farmer is most interested in seeing just what a tractor will do on his particular farm and it is not necessary to make the sale of the tractor depend on its plowing speed and its fuel consumption. As hundreds of farmers have already learned in the Eastern States, these items are often not the major considerations in operating a tractor. The farmer is most interested in seeing that a tractor will operate and continue to operate successfully and how it meets all conditions. He wants a tractor that will keep working and he will invariably select

a tractor that will operate continuously even if it uses 4 gal. per acre as compared with another tractor that claims to operate on 2 gals. per acre, but has a poor mechanical record.

Already some of the tractor manufacturers have wisely recognized the basic differences between tractor operation in the East and in the West. Some of the leaders are producing a tractor primarily intended for Eastern conditions and are not expecting too much of it in the West. In fact, they have not even demonstrated it in the Mississippi Valley. This is *prima facie* recognition of the fundamental differences in agriculture in the East and in the West.

For next year tractor manufacturers should not endeavor to sell their tractor in many parts of the East on the performances in the West. There should be one set of plowing performances for the Mississippi Valley and another for east of the Alleghenies, and in those older sections of the country where fields are small, hills are general and stones frequently encountered.

It would be unfortunate to continue endeavoring to sell a tractor in an eastern state on the basis of it plowing at 2 gal. per acre when it will use 3 to 4, and on the basis that it will plow  $2\frac{1}{2}$  m.p.h. when it has difficulty in plowing at 2 and more frequently plows at  $1\frac{1}{2}$  to  $1\frac{3}{4}$  m.p.h.

The future of the tractor and a general impression on the farmer will be much more favorable when honest conservative figures of performance are given. It is injudicious to attempt to sell a tractor to cultivate the rolling hills of Maryland on a performance made on the level stretches of Kansas or vice versa.

Hand in hand with this more conservative rating of tractor speed, tractor plowing capacity and tractor fuel consumption must come that of horsepower rating. Too many of the tractors are rated too high for general conditions. The ratings have been found too high where tractor conditions are favorable and they are correspondingly higher under unfavorable conditions in the east.

There are some tractors in parts of Pennsylvania and New York that have not been able to cultivate the areas where sold because of the hills. This trouble must not be laid to the manufacturer but rather to the merchandiser and it is poor merchandising to try to make an initial sale and place a tractor in a field it is not intended or not fitted to fill.

Let us, in these days, when tractor demand is greater than tractor supply, be conservative.

## Airplane Factories at 40% Output

Future Orders Slow in Coming  
—Production Hampered—  
Outsiders Get Orders

NEW YORK, Oct. 7.—The fact that as a total our factories manufacturing airplanes are not operating at over 40 per cent capacity is sufficient to create serious views regarding the future of the aircraft industry in America. Our total daily production of planes of all types to-day is little over sixty but our factories have capacity if given definite orders to go ahead on production to build 160 to 180 per day.

It seems almost impossible to understand why with airplanes one of the great essentials in the war we should be operating at only 40 per cent capacity. Not only is the 40 per cent figure a very distressing one but the way matters are running at present, several of our airplane factories will be cleaned up on present orders in a month or 6 weeks and by the first of the year several of the factories practically will be idle. There are other factories that have contracts that could keep them running until next July.

### No Assurances of Contracts

The factories have a very poor assurance of more contracts so that they can get materials ordered and the factory tooled up and organized for production manufacture. Since June some of the factories have been asking for such but as yet nothing is coming through and they are uncertain as to whether they are going to get a single additional contract after the present ones are completed and they face the prospect of having factories equipped for airplane production on their hands and nothing to manufacture. Instead of our factories at the first of the year operating on a 40 per cent capacity it looks to-day as if they may be operating on scarcely more than an average of 25 per cent capacity, or not that much.

There are other distressing viewpoints to the airplane situation, namely that outside factories are being given contracts whereas existing airplane factories are not. There is the case of one factory in an inland portion of Michigan that has received an order for three times as many airplane parts as some of the organized airplane factories that have been in production for a year and are now facing the prospect of not getting more orders.

This new company in question has

never previously manufactured an airplane. It has secured a new factory. It is impossible to understand just why such an outside factory should be started when the organized airplane factories are at 40 per cent capacity and looking for orders and when several of them in particular are tooled up to manufacture these same airplane parts and have been manufacturing them for nearly a year.

There are at present rumors to the effect that one or two other large establishments that have never built airplanes are to be given contracts which would seem to point to a reduction of production in existing factories. In this connection there are rumors that the Pullman Car Company of Chicago will be given contracts and others that the Brewster Company of Long Island City, automobile body builders, will be given contracts. The question is not one of getting new factories but rather of giving the existing factories contracts to go ahead on.

### Cut Passenger Car Tax to 5 Per Cent

WASHINGTON, Oct. 10.—The Senate Finance Committee has cut in half the 10 per cent tax which the House placed on the sale price of new passenger cars, motorcycles, tires, tubes and accessories, bringing it down to 5 per cent. The tax is now the same as that on commercial vehicles.

It is the intention, of the Treasury Department, if the bill is passed, to tax dealers 5 per cent on all parts in stock after they are sold, a proceeding which would be very costly and unjust to the dealers.

Alfred Reeves and Hugh Chalmers representing the N. A. C. C. have already suggested to the Senate Finance Committee that the tax should only be placed on those parts which have been shipped to dealers since September 1, 1918, when the bill was presented to the House.

The details of such a plan are now being worked out by Reeves and Chalmers, in co-operation with the National Automobile Dealers Association. This plan would be considered most equitable. Reeves has consulted F. W. A. Vesper, president of the N. A. D. A. and expects to meet the members of the dealers association here in the next few days. An objection raised by the senators to placing the tax on parts shipped after September 1 was that so long as department stores, for example, would have to pay a tax on everything taxable regardless of how long they have been in stock dealers should do likewise. Reeves and Chalmers pointed out that this would be unjust because department stores can reduce stocks at any time by means of sales while dealers must carry parts until the demand arises for them.

## Ahara Carbureter Patent Upheld

Stromberg Wins Decision Over  
Zenith, Finally Disposing  
of All Litigation

CHICAGO, Oct. 10.—Another example of a final patent decision coming almost at the end of the 17-year life of the patent is the Stromberg-Zenith carbureter controversy based on the Ahara patent owned by Stromberg, and which suit has been finally settled in favor of Stromberg by ruling of the Circuit Court of Appeals for the Seventh District of Illinois.

The Ahara patent, covering basic features in the operation of the Stromberg and a Zenith model, was issued on October 15, 1901, and so expires on October 15, 1918, or less than 2 weeks after the final decision was handed down.

By the decision the Zenith design in question is held to infringe the Ahara patent, which is sustained by the decision. The court has directed an accounting of profits by Zenith. No injunction was asked against Zenith to prohibit its continuing to manufacture this model, as the expiration of the Ahara patent is so close at hand.

The Ahara patent was issued to George V. Ahara of Beloit, Wis., and later purchased by Stromberg. It basically covers what is familiarly known as the atmosphere type of carbureter in which the richness of the mixture at high speeds is eliminated by means of an air tube in conjunction with the fuel spraying nozzle, this air tube being open to the atmosphere and also having a connection with the fuel feed in the nozzle. By this means more air in proportion to fuel is furnished at high speeds, the result being the same as that obtained by the auxiliary air valve as used on many makes of carbureters.

The controversy between Stromberg and Zenith arose over the fact that Zenith was manufacturing the same basic type under what is known as the Baverey patent No. 907,953 which covered a type of operation on the atmospheric principle and similar to that covered by the Ahara patent. The trouble seems to have been that the Zenith carbureter in question was not manufactured strictly in accordance with the Baverey patent. This was established by the ruling handed down by Judge A. L. Sanborn in the District Court of Illinois in February of 1914, at which time he stated: "If the Zenith were made substantially in accordance with the drawings on the Baverey patent (Continued on page 648)"

## Discard \$23,000,000 Aircraft Parts

### Scrap Training Planes, Engines, Trucks, Cars, Oil, Batteries and Other Parts

WASHINGTON, D. C., Oct. 8—Following announcements during the last 3 months of the discarding of certain airplane engines, parts, etc., by the War Department comes another statement that the Division of Military Aeronautics will practically discard \$23,000,000 of products made up of engines, training planes, lubricating oil, batteries, motor trucks, motor cars, motorcycles and other apparatus. No reason is given for the discarding of these parts other than that some of them have become obsolete and others deteriorated because of not being used.

The total of \$23,000,000 is not all American, as it includes 3500 French Gnome airplane engines valued at \$10,500,000, which were ordered by the French High Commission. The money to buy these was advanced by the United States to the French Government and will eventually be paid by the French. It is reported that these will be sold for junk at prices ranging from \$25 to \$120,000 per ton.

In addition to these engines there are 2000 tons of parts for them. Very few of the parts are completed. Some have not been started upon and the steel billets remain as when purchased. Others are 90 per cent finished; some are only 5 per cent finished, and some of these parts have been shipped abroad.

The Gnome engine was one time one of the most popular French types, and its manufacture in this country was carried on at the factory of the General Vehicle Co., Long Island City, which factory has recently been taken over by the Wright-Martin Airplane Corp.

The list of scrapped parts of the American airplane program includes 300 Penguin training planes valued at \$750,000. These are small primary training planes, fitted with a small two-cylinder engine which was manufactured by the Excelsior Mfg. Co., Chicago. These planes do not leave the ground but hop along. They have been used by the French for primary training, and it was on the recommendation of the French and the initiative of the army that the order for these was placed for the American training program. It seems they have not been used in our training program and apparently the army has decided that they do not fit into the present scheme of training.

The list of discards further includes 1500 JN-1 training planes valued at \$9,000,000 and 500 additional engines valued at \$750,000. These JN-1 training planes were manufactured by the Standard Aircraft Co., and there were some manufactured by the Dayton-Wright and others by the Fisher Body Co. of Detroit. They were fitted with the four-cylinder Hall-Scott engine, which does not seem to have been suited to the job, although no particulars are forthcoming. There is no reason why these planes could not be fitted with some of the eight-cylinder types of engines now satisfactorily used for training planes. It is questionable if these planes will be destroyed as they will undoubtedly be fitted with other engines.

Another list of discarded planes is 128 L.W.F. training planes valued at \$1,427,000. These, so far as can be learned, are a perfectly satisfactory type of plane, and were fitted with Thomas-Morse and Sturtevant engines. If it is a case of the engines not being adapted to the plane, there is apparently no reason why these could not be fitted up. So far as can be learned there have been no complaints regarding the engines in these planes.

In all of the ordering and deciding on this part of the airplane program the technical decisions regarding production of these different types had to come originally from the joint Army and Navy Board together with a request from the Signal Corps. The requirements originated with these organizations. The recommendations would then be presented to the Aircraft Board with its advisory power to recommend favorably or otherwise.

More than 7500 storage batteries valued at 40 cents each will be scrapped. These were found in storage practically useless through deterioration.

Inventories of the supplies of the Division of Military Aeronautics revealing these useless articles have been taken by the Surplus Inactive Supply Service of the General Staff. Additional surplus supplies, not obsolete, but not useful to the department, and valued at more than \$10,000,000, were also uncovered. These included motor cars, motor trucks, motorcycles, lumber, wood, iron and steel-working machines and oil. One hundred and fifty thousand gallons of oil worth \$75,000 and of no use to the Division of Military Aeronautics is included in the above. Four hundred and seventeen typewriters worth \$25,000 and of no use to the division are included.

At the Middletown Pennsylvania depot 9000 gal. of dope worth \$47,500 was discovered and immediately put into use. Other surplus supplies located were included.

## Export License Plan Simplified

### Priority Certificates Not Needed for Export Licenses Covering Iron and Steel

WASHINGTON, Oct. 8—The system of securing export licenses from the War Trade Board, priority certificates from the War Industries Board, or permits from the Steel Section of the War Industries Board has been simplified by new rules and regulations.

Hereafter it will not be necessary to secure priority certificates or permits from the Steel Section before requesting the applications for export licenses for the exportation of iron or iron and steel products.

All commodities listed on the export conservation list of the War Trade Board and which are also named on the preferential list recently announced by the War Industries Board will automatically be given class C priority rating by the War Industries Board in conjunction with their export licenses.

In other words the license itself will be evidence that the articles covered by it are in priority class C, if the particular commodity is listed on the preferential list of the War Industries Board.

In those cases where the Priority Committee believes the commodity for export is entitled to a particularly high rating, priority certificates for ratings higher than class C will be issued by the Priority Committee and forwarded with the export license without further request from the applicant.

Consequently, export licenses issued on and after Oct. 16, 1918, for the exportation of iron and steel or the products manufactured from them, which are not covered by special priority classification, will in themselves be permits approved by the director of steel supply, and steel or iron mills will fill the orders for the quantities specified in the export license without requesting special permission.

The War Industries Board and the War Trade Board urge exporters and manufacturers not to manufacture, purchase or produce any articles on the export conservation list for fulfilling export orders until they have secured licenses.

### Detroit Priorities Office Opened

DETROIT, Oct. 8—A priorities section of the production division of the Army Ordnance has been established in Detroit under the direction of F. J. B. Sevald. Heretofore it was necessary for Michigan manufacturers to apply for priorities to Chicago.

## Air Mail Records 100% Perfect

September Service Between  
Washington, New York and  
Philadelphia Maintained  
Without Break

Total possible number of flights..... 100  
Total possible mileage..... 10,900  
Total perfect (uninterrupted) flights  
made..... 97  
Total interrupted flights made..... 3  
Total flights defaulted on account of  
weather..... 0

Note: Number hours of dead flying for the  
month, 14 hr. 40 min.

Explanation of Tabulation:  
A. Miles flown: Leg from Washington to  
Philadelphia, 123 miles; leg from Philadel-  
phia to New York, 90 miles. Miles flown  
for the day, whether one, two, three or four  
legs of the trip have been made. The aim is  
to get exactly the number of miles flown  
in connection with the mail service each  
day. Therefore, mileage of partial trips  
should be indicated.

B. Hours of flying: To include the actual  
hours and minutes machine is in the air  
with mail.

C. Mail carried: In this column, under  
A, give pounds of airplane mail; and under  
O, give pounds of ordinary mail.

D. Per cent of performance: Round trip  
Washington-New York consists of 4 legs.

each leg valued at 25 per cent if completed  
by airplane and not by train before close of  
day.

WASHINGTON, Oct. 4—The record  
of the Air Mail Service between Wash-  
ington, Philadelphia and New York for  
the month of September was 100 per cent  
perfect.

The operation of the airplanes, con-  
structed for the Post Office Department,  
by civilian pilots of the postal service  
was inaugurated August 12. The rec-  
ord of all the flights from this date to the  
first of September, except two was 100  
per cent perfect.

The September report covers the first  
full month of operation under entirely  
civilian organization, and the round trip  
flight was made each day without a break  
in the service. The distance covered by  
these flights was 11,351 miles; the total  
time consumed 156 hours and 9 minutes,  
and the total weight of mail carried was  
15,199 lbs.

During the month there were but three  
forced landings and these were not such  
as to interrupt the flights.

## Ingenuity Needed in Airplane Repairs

"Trouble Shooters" Find Op-  
portunity to Overcome  
Temporary Difficulties

WASHINGTON, Oct. 4—Airplane re-  
pair is developing new types of motor me-  
chanics and engineers on the flying  
fields in this country, where shortage in  
airplane parts handicaps the training of  
aviators, and Yankee ingenuity is taxed  
to work out relief in some form or an-  
other. Many of these repair men, who  
are called "Trouble Shooters," soon quali-  
fy as engine experts.

At Ellington Field recently a scarcity  
of wrist pins for airplane engines de-  
veloped. A wrist pin in an engine has to  
stand a tremendous amount of strain and  
for one to break in the air would result  
in a serious accident. On account of the  
present immense demand for steel, it has  
been difficult to meet this wrist pin prob-  
lem, until a lieutenant, searching for ma-  
terial in a scrap heap, picked out an axle  
of an abandoned "jitney" automobile.  
This he treated by a special process and  
then cut and shaped the pieces into a  
number of wrist pins. They were placed  
in several engines, the cylinders contain-  
ing them plainly marked, and sent out  
for testing.

Some of these improvised wrist pins  
have had 170 hours of service and are  
still holding up as well as any others.  
The result has been a great saving of ma-  
terial and time, as well as increasing the  
number of flying hours for engines at the  
field.

### Colt-Stratton Adds D-E Trucks

NEW YORK, Oct. 7—The Colt-Strat-  
ton Co., Dodge Brothers distributor, has  
been appointed metropolitan distributor  
for Day-Elder trucks produced by the  
Day-Elder Motors Corp., Newark, N. J.

## Ordnance Output Stimulated

Well-Known Speakers Address  
Factory Workers on Win-  
the-War Subjects

DETROIT, Oct. 5—Production of ord-  
nance work in the Michigan territory is  
receiving much impetus through the in-  
troduction of an idea created by John A.  
Brown, special production assistant of  
the Detroit Section of the Ordnance De-  
partment.

Well known speakers are being sent to  
the factories engaged on ordnance work  
to give 15 to 20 min. talks to the work-  
men and foremen. About fifteen talks  
are given during the day, four or five  
speakers being at different plants at one  
time.

When the speaker arrives at the appointed  
hour the entire plant shuts down and the  
men are asked to assemble in a place large  
enough to accommodate the gathering. In  
plants where the number of employees is  
great only a few departments are closed  
down to allow the men to hear the talk.

In every plant that has been visited by a  
speaker a difference in spirit and attitude of  
his workmen has been observed since the  
talk was made. Commendatory letters have  
been received by the Ordnance Division from  
all the plants thus visited. It has been noted  
that the talks have materially stimulated  
production.

A number of points are covered in the  
speeches. The main issue is to impress upon  
the minds of the men the importance of the  
work they are doing and the aid they are  
giving in shortening and winning the war.

Some of the talks have been so effective  
that aliens have desired naturalization. The  
necessity for men to stick at their present  
work rather than change from one plant to  
another is another point that is forcefully  
emphasized.

Another form of direct appeal to the work-  
men which is proving a great inspiration to  
the men in stimulating production has been  
devised by the Timken-Detroit Axle Co.,  
Detroit, and is now being employed in its  
large shop.

A large illuminated board has been built  
along the wall of the plant on which appears  
in large figures the tonnage to be produced  
on each day of the month. This standard  
has been set at a higher figure than was ever  
hit before. On wires along the base of the  
board are two life-size figures of soldiers,  
one representing the Yank, the other the  
Hun, both of which are movable.

If the production of a day exceeds the  
standard represented by the figures on the  
board, the Yank remains ahead of the Hun,  
but should the tonnage fall below the day's  
quota the Hun is put in the lead. The posi-  
tion of these figures has a psychological  
effect on the workmen and they are ever  
striving to exceed the standard set by the  
company that the Hun may not be placed  
ahead of the Yank.

During August the output exceeded the  
average production of the previous 6 months  
by 26 per cent. September also showed a  
substantial increase.

### U. S. Employment Service Program

WASHINGTON, Oct. 4—Orders  
have been issued to the United States  
Employment Service by the Director-  
General outlining the program whereby  
replacement of men by women and the  
introduction of women into new fields of  
war industries may be intelligently di-  
rected.

Two women will be added to each of  
the Community Labor Boards which have  
been established throughout the country,  
one representing the women workers and  
the other industrial management.

When women are desired by employers  
engaged in war work for work not here-

tofore customarily undertaken by female labor the applications will be submitted to the Community Labor Board for the particular district.

The board will consider whether the work is proper for women to perform, whether conditions surrounding the job are satisfactory for women, what modifications in conditions must be made to allow employment of women, and what, if any, limitations are necessary as to the ages of the women to be employed.

The women to be selected to serve with the Community Labor Boards will include preferably those who have worked in industries, to be selected after consultation with local labor groups, and those to represent management to be selected after consultation with local representatives of management.

#### Milwaukee Gets M. T. C. School

MILWAUKEE, Oct. 7—Milwaukee has been selected as the seat of a government motor transport training school. A contract was signed Sept. 28 with the War Department by the board of directors of the Association of Commerce, by which the big State Fair Park at West Allis, a suburb of Milwaukee, will be turned into a school, accommodating 1000 soldiers at one time. Motor Hall, the fireproof building used by the Milwaukee dealers for their annual fall shows on the fair grounds, together with several other large exposition structures on the grounds, will be used to house the men. The first course will open Nov. 1, with 1000 men, and the period of training will be 30 days. On the first of each succeeding month this number of soldiers will arrive to enter the school. A large refectory will be erected immediately to fill the need for mess facilities. Otherwise the present establishment will serve all purposes.

#### Aids Less Essential Firms

WASHINGTON, Oct. 7—Legislation to authorize the war finance corporation to lend money to less essential industries which the Government has forced to curtail business during the war may be recommended to Congress soon by Secretary McAdoo. Amendments to the war finance corporation act to broaden the powers of the corporation in this and other respects have been drafted by Treasury advisers and are under discussion with directors of the corporation and members of Congress.

Most officials have agreed that the Government should extend financial aid to the curtailed industries to preserve them for after-the-war activity and minimize the general business disturbance at this time.

#### Col. Drake Nominated Brigadier General

WASHINGTON, Oct. 4—The nomination of Colonel Charles B. Drake, Chief of the Motor Transport Corps of the United States Army, as brigadier general, has been sent to the Senate by the President.

## Airplane Inspectors to Make Flights

### Officials to Fly Frequently in Planes They Have Inspected

WASHINGTON, Oct. 3—Government inspectors of airplane and aeronautical engines who work in factories or on the ground at flying fields will hereafter be required to make flights at frequent intervals in all of the planes that they inspect. This follows the inauguration of a similar plan at Fort Sill, Oklahoma, where the commanding officer requires the mechanics in charge of airplanes to take an air trip at least once a week. This order at Fort Sill applies also to the repair department of the field, with the result that on completion of repairs, the chief of mechanics responsible for the work is required to make the initial trip with the pilot trying out the machine. It is said that this insures the utmost care on the part of the mechanics and repairmen.

At Fort Sill, a day off is now granted the crew of mechanics whose engine most successfully meets the requirements of the tests each week and the competition thus engendered has resulted in a more rapid repair of engines.

#### No Indiscriminate Housing Help

WASHINGTON, Oct. 7—Unless a serious shortage of housing facilities for war workers exists in any particular industrial center and there is no other relief available, the United States Housing Corp. will not extend aid. This statement was made here recently by O. M. Eidlitz, head of the Government housing program, who stated that those communities under the impression that an unlimited national fund for housing has been voted and will be apportioned without Government scrutiny of conditions have a misconception of the plan. The Federal Government will build houses for war workers only as a measure of final relief, and not until every community concerned has exhausted its own resources. The housing corporation has arranged to secure priority orders for private housing enterprises which are inaugurated to relieve congestion in war working districts.

#### Ontario Has Car for Every 39

TORONTO, ONT., Oct. 7—That the motor traffic in this province is rapidly growing and that trucks are forming a considerable portion of this increase is indicated in the report of the Department of Public Highways for 1917, which has just been issued by the Deputy Minister, W. A. McLean. Motor vehicle registration in 1917 consisted of 78,861 passenger cars and 4929 commercial vehicles, a total registration of 83,790. This is nearly twice the registration of 1915. There is now in Ontario one car for each 39 of population. It is true in

Canada, as it is also true in the States, that agricultural communities, rather than manufacturing, contain the greater number of cars in proportion to population. In Saskatchewan the registration is one car to each twelve of population. In Ontario 23,408 cars are owned by farmers, an increase of 11,335 in 1917.

Of the 4929 motor trucks registered in Ontario last year, nearly 75 per cent were classed as one ton or less; over 97 per cent were 3½ tons or less, while less than 3 per cent were four tons and upward.

#### 89 Per Cent Dort Dealers to Continue

FLINT, Oct. 7—As a result of a canvass made of its dealers the Dort Motor Car Co. has compiled statistics showing that 89 per cent of all the dealers will stay in the automobile business regardless of whether or not they get cars. Only 6 per cent will go out of business, and 5 per cent are doubtful as to whether they will continue. Ten per cent are subject to military call. The following percentages indicate to what extent Dort dealers are interested in other lines: 67 per cent operate service departments; 38 per cent are exclusive Dort dealers; 56 per cent maintain garages; 49 per cent handle trucks; 32 per cent are agents for tractors; 60 per cent handle accessories; 75 per cent handle miscellaneous lines; 44 per cent have gas filling stations; 62 per cent handle other makes of cars and Dort.

#### Big Calcium Carbide Plant Being Established

MILWAUKEE, WIS., Oct. 5—A calcium carbide manufacturing plant costing more than \$500,000 is being established at Keokuk, Ia., by Milwaukee capital in order to meet Government requirements for material for manufacturing acetylene gas for the oxy-acetylene welding and cutting process. The work is being carried out by the Gas Tank Recharging Co., Milwaukee, which several years ago opened a small shop for recharging lighting tanks for motor cars and has since developed its business along broad lines. The capital stock, increased some time ago to \$250,000, has just been increased to \$1,000,000. The enlargement was made Oct. 1 to cover the financing of the new project at Keokuk. The plant will contain a Moore electric furnace with a daily capacity of 30 tons, two 80-ft. Stacy-Smith steel lime kilns, and a battery of eight beehive coke ovens of the Connellsville type. The works will be ready to begin operations Jan. 1. The company will continue to have its general offices and headquarters in Milwaukee, where a large compressing works is being maintained. Fred J. Pagels is treasurer and general manager.

#### Motor School at Camp Taylor to Cost \$182,233

WASHINGTON, Oct. 4—A contract has been let for construction of buildings for a motor school at Camp Taylor to cost \$182,233. The buildings will include quarters, barracks, administrative office, class rooms and a motor school.

# Tractors Fall Below Scheduled Plowing Performances

Stones, Hills and Weeds in Pennsylvania State Tests Cut Speeds 30 Per Cent and Increase Fuel Consumed

HARRISBURG, Oct. 9—Two additional reports on the Pennsylvania State tractor demonstrations held on Sept. 23 and 24 on the State Farm, near here, have been given out by the Department of Agriculture. One of these reports covers plowing by the different tractors on varied surfaces, one of the fields being perhaps as bad a plowing test as ever faced at a tractor demonstration. It was a 2-year old corn stubble covered thickly with weeds 5 ft. in height and with stones pretty generously scattered over the field. Several of the tractors had to cross a deep gully necessitating a very stiff pull when going each way of the field.

The report of this plowing by nine tractors shows that it is quite impossible to work up to the advertised speed. There was not a single tractor operating in the corn stubble that approached its advertised plowing speed. It was impossible for some of them to average one-half of their advertised speed. This was not always due to the tractor, but very frequently to the plows which gave a good deal of trouble with the tall weeds. The last column in the report of this plowing gives some indication as to the loss of time because of the plows. An official

observer accompanied each tractor throughout so that the plow stops are accurate.

Some of the tractors had particularly severe experiences with stones on this work. In this respect Parrett, Allis-Chalmers, Plowman and Plowboy suffered most. They had, with the exception of Parrett, the combination of crossing a fairly deep gully with a stiff climb at each side and each hillside with some very large rocks which were impossible to loosen with the plows. The Parrett met with very severe stone conditions.

The fuel consumption of four of the tractors which had heavy experience with stones and weeds ran over 4 gallons per acre. This is a high figure, but it represents consumption in heavy Pennsylvania plowing. While these figures may appear very severe in view of advertised fuel consumption by many companies they nevertheless give a pretty clear idea of what tractor fuel will cost the Pennsylvania farmer when he expects the tractor to do his very roughest work.

The Cleveland and Moline tractors which used gasoline pulled two plows each had fuel consumption close to 4 gallons per acre, the Cleveland running a

little over this figure and the Moline going just below it.

None of the tractors in the heavy corn stubble averaged much over .75 acre per hour, Huber and Parrett being the only ones to get slightly over this figure and several of the others averaging less than 5 acres per hour.

These figures are valuable in that they represent what a tractor can actually accomplish under very severe conditions in a small field in the east as compared with what they can accomplish on the long level stretches of Kansas or Nebraska.

On the final day of the Pennsylvania demonstrations the different tractors were given an opportunity of demonstrating what they would do in fitting the soil, for winter wheat and seeding it. In this part of the demonstrations each tractor was given approximately a 4-acre field 76 rods in length to fit and seed using whatever combination of discs, harrows and other implements considered best for the work. In these tests the assumption was that all tractors pulled approximately the same capacity of equipment, as the load when drawing these instruments is not so great as when plowing.

## Pennsylvania State Tractor Demonstration—Fitting and Seeding Records Tuesday, September 24, 1918

No.	Make of Tractor	Rating		Acres Fitted and Seeded	Gallons Kerosene Used	Gallons Gasoline Used	Gross Time	Net Time	Tractor Stops	Implement Stops
1.	Emerson-Brantingham	12-20	Emerson 8-ft. double-disc and spike-tooth harrow .....	3.886	4.56	.687	1:50	1:50	0	0
			Emerson grain drill, 12 x 7 .....	3.886	5.375	.375	2:34	2:34	0	0
2.	Knickerbocker	22	Withdraw							
3.	Reed	12-20	Withdraw							
4.	Parrett	12-25	Bissell 8-ft. double-disc and Superior grain drill, 11 x 8 ...	3.886	5.00	.125	2:22	2:22	0	0
5.	I. H. C.	8-16	Withdraw							
6.	Cleveland	12-20	Oliver 8-ft. double-disc and Oliver 8-ft. pulverizer .....	3.886		4.25	1:54	1:26	0	28
			Massey-Harris grain drill, 10 x 7 .....	3.886		4.00	1:48	1:23	25	0
7.	Case	9-18	Superior 8-ft. double-disc and Oliver pulverizer .....	3.886	4.00	.125	1:25	1:19	0	6
			Superior grain drill, 11 x 8 .....	3.886	4.00	.375	1:40	1:34	0	6
8.	Huber	12-25	Oliver 8-ft. double-disc and Oliver pulverizer .....	3.886	4.187	.375	1:27	1:27	0	0
			Superior grain drill, 11 x 8 .....	3.886	3.00	.187	1:09	1:04	0	5
9.	I. H. C. Titan	10-20	Withdraw							
10.	Plowman	15-30	Oliver 8-ft. double-disc .....	3.886	3.25	1.00	1:53	1:53	0	0
			Emerson grain drill, 12 x 7 .....	3.886	4.437		1:48	1:48	0	0
11.	Plowboy	13-30	Oliver 8-ft. double-disc and Oliver pulverizer .....	3.886	4.50	.50	2:09	2:09	0	0
13.	Waterloo	12-25	Withdraw							
14.	Frick	12-25	Massey-Harris 8½-ft. double-disc and pulverizer .....	3.886	4.56	.25	1:52	1:41	11	0
15.	Allis-Chalmers	10-18	Bissell 8-ft. disc and Oliver pulverizer .....	3.886	3.50	1.50	2:06	2:00	0	6
			Superior grain drill .....	3.886	3.00	.50	1:55	1:55	0	0
16.	Moline	9-18	Moline 7-ft. double-disc and roller .....	3.886		5.50	1:43	1:43	0	0
			Superior grain drill, 11 x 8 .....	3.886		4.00	1:36	1:36	0	0

These records show the fuel used in cultivating and seeding the 4 acres which varied considerably. Generally it approximated 1 gallon per acre although in several cases it fell below this, Allis-Chalmers, Plow-Man and Huber getting below this figure. With the Cleveland and Moline using gasoline, the consumption approximated 1 gallon per acre.

#### Detroit Subscribes Three-fifths of Quota

DETROIT, Oct. 7—Nearly three-fifths of Detroit's quota of \$74,000,000 was subscribed for at the close of the first week of the Fourth Liberty Loan campaign. The subscriptions now total approximately \$56,000,000, with \$28,000,000 still to be subscribed. Employees of the factories have pledged in excess of \$6,000,000 of the total reported up to Saturday noon, and they are looked to for at least \$10,000,000 more this week.

Henry Ford and the Ford interests announced a subscription for \$10,000,000. Seven million dollars will go to the Wayne County quota, while \$3,000,000 will be credited to branch factories. This is \$4,000,000 more than was subscribed in the last loan, including factory assembly branches. The Ford Motor Co.'s subscription, taking in the employees of the Highland Park plant and the shipbuilding yards, is given at \$6,000,000.

#### Chalfant Engages in Export Trade

NEW YORK, Oct. 7—E. P. Chalfant, one of the pioneers of the automobile industry, has resigned as eastern division manager of the Anderson Electric Car Co. to become general manager of Automotive Products Corp., an export house organized in 1917 by the American Steel Export Co. for the purpose of specializing as direct foreign representatives for American manufacturers of automotive products of every nature.

## Third B Truck Order for Detroit

### Makers in Michigan-Ohio Territory to Make 35% of Latest Government Contract

DETROIT, Oct. 8—Exactly 35 per cent of the order for Class B trucks recently placed by the Government will be produced in the Michigan-Ohio territory. Every manufacturer is rapidly adjusting his facilities to get into early production, and it is expected that within 10 days all will be engaged on this work. The orders in this section represent a value of \$26,250,000. The companies awarded contracts in Michigan and Ohio are given in the following tabulation with their respective quantities of trucks to be produced:

United Motors .....	500
Signal .....	500
Denby .....	1,500
Lewis-Hall .....	500
Republic .....	2,000
Wilson .....	500
Clyde .....	500
United States Motor Truck.....	1,500
Gramm-Bernstein .....	2,000
Standard .....	750
Midland .....	500

Companies in other parts of the country awarded contracts follow:

Vim .....	500
Winther .....	500
Rockaway .....	1,000
Diamond T. ....	2,000
Bethlehem .....	1,500
Rowe .....	500
Sterling .....	750
Indiana .....	1,500
Maccar .....	500
Service .....	750
Atterbury .....	750
Velle .....	2,000
Selden .....	2,000

Of those truck manufacturers awarded contracts in Michigan and Ohio nearly 75 per cent have not had Government work within their walls.

#### General Motors to Acquire United

NEW YORK, Oct. 9—Negotiations covering the absorption of the United Motors Corp. by the General Motors Corp. are practically complete, and as was told in AUTOMOTIVE INDUSTRIES early in February of this year, the United Motors as a separate company, will shortly be dissolved. A special meeting of stockholders of the United Motors Corp. will be held Oct 30 to vote on a plan calling for the dissolution of the company and to consider an offer of the General Motors Corp. to acquire all assets and liabilities of the company. The consideration will be an exchange of 110,164 shares of common stock and 330,492 shares of preferred stock of the General Motors Corp. If such a plan is approved, the assets of the United Motors Corp. remaining after debts are paid, will be distributed among the stockholders and the corporation dissolved.

#### Akron Goes "Over the Top"

AKRON, Oct. 7—Akron has exceeded its fourth loan quota of \$10,645,050 by more than \$100,000, and has achieved a distribution fully 50 per cent wider than in the third loan. A total of 65,000 subscribers were reported. When all pledges are completed it is expected that not only will the total subscribed jump several hundred thousands, but the Akron Liberty Loan committee is confident the total of subscribers will be above 80,000. Two million one hundred thousand dollars each was subscribed by the management and employees of the Good-year and Goodrich companies.

### Pennsylvania State Tractor Demonstration—Second Day's Plowing Monday, September 23, 1918

No.	Name	Rating	Plows	Entered Speed	Speed in Work	Acres Plowed	Acres per Hour	Gallons Kerosene per Acre	Gallons Gasoline per Acre	Gallons Kerosene Used	Gallons Gasoline Used	Gross Plowing Time	Net Plowing Time	Tractor Stops	Plow Stops

NOTE.—Tractors No. 2, 4, 6, 8, 10, 11, 15, 16 plowed in a two-year-old corn stubble field that was overgrown with weeds 5 feet high, contained many large stones in some sections and had several gullies and grades. This was the hardest plowing test during the entire demonstration. All other plowing shown on this report was done on sod fields. The corn stubble plot was divided for 1 hr. 15 min. work for each machine. Tractor No. 2 withdrew during the day, and tractors No. 5, 9, 13 did not report, and tractor No. 1 was engaged in work which appears on Table No. 1.

## Beware of Motor Stock Offers

### Treasury Department Issues Warning Regarding Speculative Securities

WASHINGTON, Oct. 2—Ten promoters of questionable speculative motor company enterprises offering securities on the market are under investigation by the Capital Issues Committee of the Treasury Department. These companies will probably be blacklisted if they do not cease their present activities. "Continued offering of the stocks or bonds," it is said, "will result in the advertising of the enterprises as working against national policies during the war." Blacklists will be published and displayed by post offices, chambers of commerce, district attorney's offices, etc. These motor companies are offering about \$30,000,000 worth of securities to the public. One, in Minnesota, has already sold \$2,000,000 worth of stock, 50 per cent of which went to salesmen as commission. Liberty bonds were taken in payment and then sold on the market.

Private investors desirous of conserving credit for war purposes directly or indirectly contributing to the war are asked by the committee to refuse to buy stocks or bonds which have not been approved and to inform the Capital Issues Committee, Treasury Department, Washington, D. C., of any offerings of stocks or bonds which have not been so approved.

The Capital Issues Committee was organized to prevent the offering of stocks or bonds which have not been so approved.

The Capital Issues Committee was organized to prevent the offering of stocks or bonds that are not compatible with the national interest during the emergency, and which will result in the advertising of the enterprises working against national policies during the war.

It is also investigating 250 oil companies which are offering more than \$100,000,000 worth of stocks, and other concerns violating the regulations.

### Acid Rulings Modified

WASHINGTON, Oct. 4—The Price Fixing Committee of the War Industries Board has modified its ruling of Sept. 26 as follows: "The maximum prices for acid below 92 per cent H<sub>2</sub>SO<sub>4</sub> shall be figured on the price for 60 degrees Baumé Sulphuric acid, and above 92 per cent H<sub>2</sub>SO<sub>4</sub> on the basis of 66 degrees Baume Sulphuric Acid."

### Mechanical Engineers Establish Cleveland Section.

CLEVELAND, Oct. 3—The American Society of Mechanical Engineers has established a section in Cleveland which will be known as the Mechanical Section of the Cleveland Engineering Society. This new section includes a territory having a society membership of approxi-

mately 260. A joint meeting of the Council of the A. S. M. E. will meet at Indianapolis on Oct. 25-26 and at this meeting will gather the Indianapolis, Cincinnati, St. Louis, Chicago, Milwaukee, Detroit and Cleveland sections. The Indianapolis section of the Society of Automotive Engineers, the Indiana Engineering Society and the Indianapolis-Lafayette section of the American Institute of Electrical Engineers have also been invited. Headquarters will be at the Claypool Hotel.

### Goethals a Member of the War Industries Board

WASHINGTON, Oct. 5—Major General George W. Goethals, Assistant Chief of the General Staff, and Director of the Division of Purchase, Storage and Traffic, has been made a member of the War Industries Board. General Goethals takes the place on the board formerly filled by his assistant, Brigadier General Hugh A. Johnson, who has been assigned to a field brigade for active service. General Johnson's position as assistant to General Goethals is being filled by Gerard Swope of New York.

### Motors Division, Vehicle Section, Q. M. C. Has New Address

WASHINGTON, Oct. 5—The Motors Division, Vehicle Section, Quartermaster Corps, which has charge of the procurement of motor vehicles for the Army, excepting tanks, tractors and airplanes, has moved from Seventh and B Streets to Nineteenth and B. The Motor Transport Corps under Brig. Gen. C. B. Drake, which has complete charge of operation, maintenance, engineering and also the technical supervision of all of the trucks and motorized vehicles of the Army, will remain at Seventh and B Streets.

### Complaints Against Misleading Advertising

WASHINGTON, Oct. 2—Formal complaint has been filed against the Silvox Co., South Bethlehem, by the Federal Trade Commission, which states that it has reason to believe the company has employed misleading advertising. The complaint alleges the Silvox Co., following a test of its spark plugs by the United States Bureau of Mines, misrepresented in its advertising that the Bureau of Mines had "certified" the plugs. The concern is cited to appear before the Commission in Washington, Nov. 13.

### Owners Ask for Adequate Supplies

REGINA, SASK., Oct. 5—Automobile owners of Saskatchewan are about to ask legislation requiring a full line of automobile supplies for all makes to be carried in at least one place in the Province, so that they may be assured of securing repairs quickly when desired. They will also ask that the full line of supplies for automobile makes that have been withdrawn from the market be carried for at least three years.

## Utz Completes Work in France

### Resumes Place with Standard Parts Co. After Year on Special Service

WASHINGTON, Oct. 5—Jack Utz, formerly in charge of engineering for the Motor Transport Service of the Quartermaster Corps under Christian Girtl, who went to France for the service to aid in the construction and organization of the Motor Transport depots there, has returned to Washington.

Mr. Utz has completed his work for the Quartermaster Department, having rounded out the full year for which he was engaged and during which he was released by the Standard Parts Co., and has again resumed his connection with that company, under Mr. Girtl.

The motorized vehicle equipment with the American Expeditionary Forces, according to Mr. Utz, is not entirely complete, as there are less than 30,000 motorized vehicles. This has been caused by the lack of shipping tonnage, priority having been given to trucks rather than repair parts, and to repair parts rather than to machine shop equipment, with the result that machine shop equipment for making repairs has been sent over in negligible quantities.

### Salvage Depot Operated

A huge salvage depot employing 6000 men is operated under Colonel Hegemann of the Quartermaster Corps. The Motor Transport Corps is headed by Brig. Gen. H. L. Walker as the Director of the Corps with Colonel E. L. Rogers as Deputy Director under Gen. Walker.

Organization of the Motor Transport is just taking place. A new kind of organization was worked out, partly with the aid of Mr. Utz, and is now being enacted. A liaison arrangement is planned so that officers of the Motor Transport Corps in France will exchange with officers of the Motor Transport Corps in this country, bringing to each of the Corps the knowledge of the activities on the different sides of the ocean.

The British and French truck services are practically perfect. Both armies have as many vehicles as they require per corps or division. The French have established a group plan operating throughout the country and far from the lines by which small groups of trucks are established as depots in different communities and are directed by headquarters to carry freight or men as the case may be.

### No War Hospital at Speedway

CHICAGO, Oct. 4—Work of turning the Chicago Motor Speedway at Maywood into a permanent army hospital, which has been under way for several weeks, has been halted by the authorities at Washington. The plan for turning the plant into a reconstruction hospital for men maimed in the war was rejected yesterday.

## Gasless Sundays to Continue

Statistics Show Fuel Conservation to Be Necessary for Some Time

WASHINGTON, Oct. 5—Gasolineless Sundays will continue for the present, according to an announcement made by the Fuel Administration to-day. Statistics on the available supply of gasoline, it was said, show the necessity for a continuance of the motorless period.

Following a suggestion from Governor Samuel McCall of Massachusetts that the restriction from Sunday automobiling should be removed to allow the public to use their automobiles and secure the fresh air that would combat the epidemic of influenza which is prevalent in the eastern states, Fuel Administrator H. A. Garfield made public an opinion from Brigadier General Charles Richard, Acting Surgeon General, United States Army, that automobiling would not influence the influenza epidemic one way or another.

The total available gasoline in the United States outside of California for the week ended Sept. 23 was 3,302,000 barrels of motor gasoline and 281,000 barrels of aviation gasoline, announced Mr. Garfield. This, it was stated, is a decrease from a stock of 11,000,000 barrels on April 1 and 8,000,000 barrels on Aug. 1.

The gasolineless Sundays, according to the Fuel Administration, have resulted in a saving of between 450,000 and 500,000 barrels of gasoline. The Fuel Administration states that 300,000 barrels or 10 shiploads of gasoline have been shipped abroad, which would otherwise have not been available, as a result of the gasolineless Sundays.

### Janesville Machine Co. Building Motor Cultivator

JANESVILLE, WIS., Oct. 5—The Janesville Machine Co., which recently was acquired by the General Motors Corp., already has arranged to enlarge its line of products by undertaking the manufacture of a motor cultivator, which is the first of a number of power machines to be built in quantities at Janesville. Work on the new tractor plant at Janesville is progressing well and it is hoped that the actual production of Samson Sieve-Grip machines will be started shortly after Nov. 15.

### 40,000,000 Barrels Fuel Oil Wasted

WASHINGTON, Oct. 5—Of 160,000,000 barrels of fuel oil used last year, 40,000,000 barrels were wasted because of inefficient operation of plants and improper firing. The fuel oil wasted was sufficient to operate the railroads of the United States for one month, and five times the amount of fuel oil necessary for the Army and Navy. It represents a value of \$140,000,000 yearly. This waste has been discovered by experts of the

Bureau of Mines, who have been co-operating with the Fuel Administration in a survey of the use of fuel oil for power purposes in the United States. They state that the 40,000,000 barrels of fuel oil lost each year is equivalent to 10,000,000 tons of coal.

The Bureau of Mines as a result of the investigations has compiled a handbook for boiler plants and locomotive engineers, giving instructions in the efficient use of fuel oil. These handbooks will be forwarded to all plants using fuel oil as soon as they are completed.

### Kansas City Manufacturers Apply for War Contracts

KANSAS CITY, Oct. 4—A group of Kansas City manufacturers has formed an organization, with James Lapsley, vice-president of the Beggs Motor Car Co., as chairman, to secure war contracts which the firms are especially adapted to fill. The group is aiming at contracts for truck bodies in particular. Included in the organization are the Huttig Mill Work Co. and the Federal Sash & Door Co., the Kansas City Forging Co., J. A. Elberg, the Anderson Coupling & Supply Co. and Western Trailer Co. and C. J. Welch, president and general manager of the Western Trailer Co. The idea is that each member of the group would assemble a certain proportion of the bodies ordered. The group is known as the Kansas City Association of Truck Body Builders. Other firms in the city with limited capacity shops of various kinds have indicated their willingness to take over the assembly of small quantities under any orders secured.

### American Red Cross Needs Drivers and Mechanics

CHICAGO, Oct. 3—Eighteen hundred men familiar with the mechanism of the automobile are needed by the Red Cross for overseas duty immediately following a mechanical and military training of from three to five weeks. This training will be given in barracks known as Camp Scott, Chicago. Pay will be \$40 per month, half pay being given while undergoing instruction and in addition a paid up life insurance policy for \$1,000 will be handed each man on embarkation. All men, except those in class 1 of the draft, are eligible. Minimum service is for a year and maximum is for the duration of the war. Recruiting headquarters are at 528 Peoples Gas Building, Chicago, and the new department is under the direction of Major H. P. Harding.

### Hupmobile Distributors to Retire

NEW YORK, Oct. 7—Charles E. Reiss & Co., Hupmobile distributors, are shortly to retire from the automobile trade, the company's sales and maintenance business having been taken over by the Marmon Automobile Co. of New York. The sales and service staffs of the two companies will be consolidated and all business will be carried on from the present Marmon headquarters.

## Lubricate Whole Car From One Point

Reservoir and Pumps Substituted for Grease Cups—Applied to Any Car

BRIDGEPORT, CONN., Oct. 7—A new system of chassis lubrication for cars and trucks by which all spring shackles, brake bearings, rear axle spring pads, steering heads, pedals, etc., can be supplied simultaneously with oil under pressure by turning a small lever conveniently situated in front of the driver's seat is being manufactured by the Smith & Egge Mfg. Co., Bridgeport. The invention, which is the subject of a patent by B. H. Skelly of the Smith & Egge Co., consists of a combination reservoir and multiple plunger pump located under the front seat or other central position, from which proceed a number of flexible steel tubes to the several points requiring lubrication on the chassis.

A car fitted with the system has been in operation over a year with satisfactory results. The lubricator as made at present has thirty separate plungers and corresponding tubes, displacing a like number of grease cups. The plan is that of applying the system to cars by simply removing the grease cups and screwing into their places the elbows or unions which are attached to the ends of the flexible tubes. A spring ball check in each of these unions prevents any leakage of oil over that required for lubrication by closing the tube as soon as the pressure is released.

Selling arrangements are not yet completed but it is proposed to establish agents in large towns who will fit the system. As supplied from the manufacturer the system includes the lubricator, oil unions, clips and about 200 ft. of flexible steel tubing.

This lubricating system marks the entry of the Smith & Egge Co. into the automotive field, though it has been manufacturing force feed lubricators for stationary engines for many years.

### New Amazon Cord Tire

AKRON, Oct. 7—The Amazon Rubber Co. is marketing a new type of cord tire under the trade name "Amazon Cord Supertire." The tire has a black tread and gray side wall, and is made in these sizes: 34 x 4½, \$67.25; 36 x 4½, \$70.55; 35 x 5, \$83.60; 37 x 5, \$87.60; 36 x 6, \$109.50.

### Lane Gets Priority Order

KALAMAZOO, Oct. 7—The Government has granted the Lane Motor Truck Co. a priority order permitting it to build a quota of 70 trucks a month for the balance of 1918. The company has a large number of orders on its books for trucks to be used by concerns in essential war work. A production of one truck a day has been reached, which number will be doubled within a week.

## August Exports Gain 3.8% on July

Figures Are 5.7% Better Than Those of the Same Month Last Year

	1918		1917	
	Cars	Value	Tr'ks	Value
Aug.	2,710	\$2,818,259	909	\$2,337,904
July	3,442	\$3,624,870	601	\$1,527,519
				2,771,193
	1917		1917	
Aug.	3,605	\$2,909,606	929	\$2,677,695
				2,195,564

WASHINGTON, Oct. 7—Exports of passenger cars, trucks and parts (not including engines and tires) during August were valued at \$8,228,919, an increase for the month of 3.8 per cent as against the figures for July. The increase in comparison with August of last year is 5.7 per cent.

Passenger cars show a falling off, but the number of trucks exported during August has increased no less than 51 per cent in comparison with July, although slightly below August, 1917.

Taking the totals for the first eight months of the present year, including those relating to engines of various types, and comparing them with the figures covering a similar period of 1917 there is a slight falling off shown, the 1918 totals being nearly 2 per cent below those of 1917.

It should not be forgotten that the figures given do not include airplanes exported for military purposes. The export of tractor engines continues to increase steadily, and, as was the case in July, Australia is our best customer for passen-

ger cars in point of number at any rate. Taking the eight months' totals Canada is far in front as an importer.

### Receiver for Crow-Elkhart

SOUTH BEND, Oct. 5—A petition asking that the Crow-Elkhart Automobile Co. of Indiana and Arizona be declared a bankrupt and a receiver be appointed to take charge of the company's property and equipment at Elkhart, Ind., operating the factory for a limited time, has been filed in the Federal Court at Indianapolis by the Charles L. Monger Company and the Isbell Lumber and Coal Company, and Ora Neff of Lockhart. Judge Harmon of the Elkhart Superior Court has appointed M. U. Demarest receiver. It is claimed that the company has property and material worth \$350,000, and that a receiver named by the Federal Court would be to the advantage of the creditors. It said 150 cars would be manufactured from the materials on hand and that the plant could operate until Jan. 1, 1919.

### Ahara Patent Upheld

(Continued from page 640)

it seems there could be no infringement because there would never be a sub-atmosphere in the air tube in conjunction with the fuel nozzle. But the infringing Zenith device restricts the opening in the upper part of the air tube to one or two very small holes, while the patent drawings show the right-hand leg of the air tube very much enlarged with its upper end either wide open or covered only with a wire screen." The decision just handed down apparently ends the patent litigation.

## Truck Exports Show 95% Increase

August Exports from New York Show Total Increase of Over 10 Per Cent

NEW YORK, Oct. 7—The most satisfactory feature of August's exports from the Port of New York is the remarkable increase in the number of trucks shipped as compared with the figures for the previous month. During July a total of 239 trucks, valued at \$741,132, were exported through this port. The August figures are 443 trucks, valued at \$1,450,456, an increase of 85 per cent in number and 95 per cent in value.

Passenger cars show a slight falling off in number and also in value, and the value of parts is also lower, but the total exports for August show a gain of practically 10 per cent over those for July, the respective figures being \$3,834,346 as against \$3,486,980.

France is still our best customer for both passenger cars and trucks, but England leads as a buyer of parts. Countries to which automotive exports were made during August, and which were not represented in the July list, are China, Egypt, Iceland, Sweden and European Russia and Hong Kong. Spain continues to import on a satisfactory scale, and it is considered that this country offers a market worth careful cultivation.

### Rules for Exports to Sweden

WASHINGTON, Oct. 7—Exporters in the United States, before filing appli-

## Exports of Automotive Equipment for August and Seven Previous Months

	Month of August				Eight Months Ending August, 1918			
	1918		1917		1918		1917

cations for export licenses to Sweden, must secure advice from the prospective Swedish importer that an appropriate association or the Statens Handels Kommission has issued a certificate covering the proposed consignment.

The American exporter must secure the number of the certificate from the importer, and this number must be specified on the application for the export license.

Exporters are required to state on the application the name of the person or firm in whose favor the import certificate was issued.

The War Trade Board urges that purchases for export to Sweden and arrangements for the manufacture of any articles for export to that country should not be made until the export license has been secured.

### Urge B3 Priority For Trucks

NEW YORK, Oct. 5—That a B3 priority rating for truck manufacturers would do much to put them in position to get needed materials; and that the steel situation may change over night and be greatly relieved, were the two important matters which were brought before the meeting of the Motor Truck Committee of the National Automobile Chamber of Commerce on Thursday afternoon. There were 67 truck manufacturers in attendance, some of whom were not members of the N. A. C. C.

Charles C. Hanch, chairman of the Automotive Products Section of the War Industries Board definitely recommended a B3 priority rating for truck manufacturers, upon the plea that the truck is essential to both war and business and for this reason the industry must be continued. He stated that in consequence of a careful review of appeals made by certain truck manufacturers from the curtailment order of the War Industries Board, these makers had had their apportionments increased by approximately 50 per cent.

Hanch stated that he was not in position to know the attitude of the Priorities Division with regard to the production of trucks after Jan. 1, 1919. He hoped, however, that by Dec. 1 of this year he would have a decision upon which in conjunction with inventories filed by makers, to base an apportionment for the first six months of 1919. The production of new models will not be countenanced under any consideration, nor will the conduct of experimental work be looked upon with favor.

The statement that the steel situation may be very considerably relieved over night was made by George Graham, chairman of the Motor Truck Committee of the N. A. C. C. Such relief would hinge, according to information given Graham, by a steel maker of international reputation, upon the advance of the Allies by so little a distance as 12 miles on certain fronts. Such an advance would put the Allies in possession of the richest ore mines in the world—mines which would take care of all the steel requirements of the Allies, thus releasing great quantities of steel for commercial use.

## August Exports to Latin America

### New York Ships Automotive Products Valued at \$1,150,-802 During Month

NEW YORK, Oct. 7—During the month of August 591 passenger cars valued at \$721,056, 48 trucks valued at \$103,172 and automotive parts valued at \$326,575 were shipped from the port of New York alone to twenty Latin-American countries. The total value of these was \$1,150,802.

These figures are included in the table on this page, which gives the totals by countries for the eight months ending

Aug. 31, 1918. Chile holds the lead as a buyer of passenger cars and is followed closely by Uruguay in point of numbers, although not in average cost per car. Cuba alone seems to realize to the full the advantages of the truck as a means of rapid and economical goods transportation and affords a point of comparison with, for instance, Argentina, with her enormous possibilities for speeding up the transportation of meat products by the use of this form of transport.

### Republics Go to Japan

ALMA, MICH., Oct. 7—For the period from Jan. 1 to Aug. 15, the Republic Motor Truck shipped to Japan a total of 76 trucks. Preparations are now under way for a shipment of 152 trucks to reach the Pacific coast before Oct. 15 to be forwarded by boat a few days later.

## Flying by Compass Field Training

### New System of Independent Courses on Triangular Route Inaugurated

WASHINGTON, Oct. 7.—To instruct flying by compass at the flying fields in this country, a combination field triangle has been inaugurated, using Kelly Field, Texas, and two of the five Texas cities where good landing fields have been laid out as the other points. The routes require 6 hours of flying time and cover 275 miles each. Using all five cities in Texas in conjunction with Kelly Field five triangles have been formed as follows: Kelly Field, Flatonia and Austin; Kelly Field, Flatonia and Beeville; Kelly Field, Austin and Victoria; Kelly Field, Victoria and Beeville; and Kelly Field, Beeville and Uvalde.

The first plane leaves Kelly at 7 a. m., flies to the first point in the course by compass, checking up the route and locating the landing field by map. The others follow at intervals of 10 minutes, which is considered ample time to necessitate each pilot's flying his own course rather than merely trailing the plane ahead. The second leg of the course is flown in "V," bombing, or triple-"V" formation, and the third, the return to Kelly Field, is flown in the same manner as the outgoing trip. The first and last ships of the 12 are piloted by instructors, each carrying a troubleshooter. The others are flown by students. All planes are equipped with compasses.

Advanced cross country flying thus serves as a combination and development of two earlier stages, primary cross country and primary formation, and accustoms the student to long hours in the air. Flying part of the route by compass gives the pilots experience in laying out their own courses and at the same time prevents the severe strain which 6 hours of continuous flying would give.

All who receive instruction on the advanced cross country stage are R. M. A.'s, Reserve Military Aviators, awaiting transfer. Every effort is made to keep this time awaiting orders from being wasted, and to continue their training as long as they remain at Kelly Field.

### Dort Speeding War Work

FLINT, Oct. 5.—The Dort Motor Car Co. will start production this month on its order for the government for

1-ton trucks. Production on the new order for cargo trailers has been started and the company reports that 700 government kitchen trailers have already been shipped.

### Seven Deaths From Flying

WASHINGTON, Oct. 7.—Seven deaths resulted for the week ended Sept. 28 at flying fields in this country. This represents one fatality for every 2526 hours flown, or 202,080 miles of air travel. Following is the summary:

Baron Field, Everman, Texas.....	1
Bolling Field, Anacostia, D. C.....	1
Carlstrom Field, Arcadia, Fla.....	1
Ellington Field, Houston, Texas.....	1
Mather Field, Sacramento, Cal.....	1
Talliaferro Field, Fort Worth, Texas.....	2

### 1,694 De Havillands and 8,216 Liberty Engines Produced

WASHINGTON, Oct. 4.—Two hundred and thirty-four DeHaviland airplanes were produced last week, bringing the total production to 1694. Liberty engine production totaled 8216 up to last week. These figures were presented to the House Military Committee at a conference to-day.

Seventeen British bombing airplanes with their pilots in position and ready for work

## Army Balloon Corps Increased

### Demand from Expeditionary Forces Renders Additional Crews Necessary

WASHINGTON, Oct. 7.—The Balloon Corps of the Army is to be enlarged by 25,000 men and 1200 officers, owing to the increased demand from the American Expeditionary Forces for balloon crews. The present Balloon Corps totals 11,000 men of all ranks.

Authority has been obtained by the Air Service from the General Staff to induct men of draft age and to transfer officers from the other branches of the service. This increase will create many vacancies in the grades of colonel, lieutenant-colonel, major, captain and lieutenant.

Enlisted men and civilians who apply for officers' examinations will be required to take the cadet course of from 3 to 5 months, and training camps for this purpose will be conducted this winter in the South and on the Pacific Coast. The schools already established for this purpose are located at Old Point Comfort, Virginia; San Antonio, Texas, and Arcadia, California, near Los Angeles.

In addition to the important role played by the balloon in the control of artillery fire, it is now being used with infantry, a caterpillar mount for the winch by which the balloon is controlled having been successfully used on the front. This portable winch makes it possible for balloon companies to even keep up with infantry advances for observation and direction of attack.

In addition to the opportunities for immediate promotion, officers who join the balloon service will receive the benefit of flying pay when they actually do the work of observers and make flights in connection with army operations. Flying pay is 25 per cent of the base pay of an officer.

### Chicago-St. Louis Barge Service

ST. LOUIS, Oct. 4.—It has been announced officially here that a dependable barge service between this city and Chicago will open shortly. The freight rates will be about 80 per cent of the railroad rate and the bill of lading will be as useful as commercial paper. The service will be under direction of the Government, and will be through the Illinois and Michigan Canal, the Illinois River and the Mississippi.

C. W. Holloway has been appointed district manager of The Cleveland Tractor Co. for the southeast with headquarters in Atlanta, Ga., where offices have been established in the Healey Building. The territory comprises Georgia, Alabama, Florida, North and South Carolina and that part of Tennessee east of the Tennessee River.

G. D. Jones has been appointed sales engineer of The Cleveland Tractor Co., Cleveland. He has been connected with the tractor industry for the past 9 years, being associated with the State Department of Engineering of California for 6 years of this period. He will have charge of experimental work in developing plans and methods for increasing the efficiency of the tractor and its field of usefulness.

F. N. Morgan has been appointed district manager for the Cleveland Tractor Co. for the southwest with offices in the Colcord Building, Oklahoma City. The territory included in this district comprises Oklahoma, Texas, New Mexico, Arkansas, Mississippi, Louisiana and that part of Tennessee west of the Tennessee River. Prior to his present connection Mr. Morgan was assistant manager of the Studebaker Corp., St. Louis branch.

A. H. Pearsall has been appointed district manager by the Cleveland Tractor Co. and has established offices in the People's Gas Building, Chicago. The territory comprises the greater portions of Illinois, Wisconsin, Iowa and Missouri. Mr. Pearsall was associated with the Studebaker Corp. for 7 years.

#### Grip Hits Boston Trade

BOSTON, MASS., Oct. 5—Spanish influenza began taking its toll from among the automobile trade here this week. I. A. Howell, president of the Howell Motor Co., agent for the Liberty car, who had been ill for some time, was the first to go. Philip Hawley, formerly manager of the Studebaker branch, and later of the Hawley-Cowan Co., New England distributors for Saxon cars, also died. H. R. Cox, who came here from Rochester, N. Y., to take charge of the Bearings Service Co., was the third to go within the week. A number of men in the mechanical departments of the motor stations have been very ill and some of them died. John H. Johnson, of the Buick, who was the big factor in putting over the drive for members for the N. A. D. A., caught cold at a Liberty Loan meeting and he hurried away to Poland Springs, Me., to recuperate.

#### Order 25,000 "B" Axles

WASHINGTON, Oct. 8—The Motors Division of the Quartermaster Corps has placed orders for axles for the B 3-ton war truck as follows:

Timken-Detroit Axle Co., 15,000 axles.

Sheldon Axle Co., 5000 axles.

Standard Parts Co., 5000 axles.

Price to be paid by the Government for these axles is understood to be \$880 each.

## Men of the Industry

### Changes in Personnel and Position

#### Will Consider Exports to Denmark

WASHINGTON, Oct. 8.—Applications for export of all commodities except cereals and fodders to Denmark will now be considered by the War Trade Board. Exporters applying for licenses should use application form X and supplemental information sheet X-105. Exporters in the United States before applying for licenses must obtain advice from the prospective Danish importer that an import certificate has been issued for the consignment either by the Merchants' Guild of Copenhagen or the Danish Chamber of Manufacturers. Commodities exported to Denmark may be shipped only on vessels flying the Danish flag. Export licenses should be secured before any articles are manufactured for export to Denmark.

#### Coal Production Increases

WASHINGTON, Oct. 8.—Production of bituminous coal during the week ended Sept. 28 was 13,043,000 tons, an increase over the same period of 1917 of 1,863,000 tons or 16.7 per cent. This is the second time in the history of coal production that the output exceeded 13,000,000 tons in a week. At present there is a shortage of 10,897,000 tons of coal as against the estimates of coal requirements for the year. Anthracite production for the week ended Sept. 28 was 2,071,000 tons, an increase of 224,000 tons over the preceding week and 65,000 tons over the corresponding week of last year.

#### Dixie Highway Opens Oct. 15

MONROE, MICH., Oct. 7.—Completion of the Dixie Highway, which extends between Detroit and Toledo, through Monroe county, will be celebrated by the Detroit Automobile Club, Oct. 15 at Monroe and South Rockwood. Michigan State officials, including probably Governor Sleeper, Highway Commissioner Frank Rogers, members of the state highway preparedness board, road officials of Wayne and Monroe counties, Michigan, and Lucas county, Ohio, as well as city officials will participate in ceremonies marking the formal opening of the highway. A delegation of army officers may also attend the dedication, as the new road is of the greatest importance to the Motor Convoy service which has been sending motor trucks out of Detroit to France for the past year.

C. T. Schaefer, formerly chief engineer of the Globe Motor Truck Co., is now chief engineer of the Anvac Mfg. Co., Anderson, Ind.

S. V. Norton, manager of the truck tire sales of the B. F. Goodrich Co., Akron, is one of the several men to whom Gov. Cox of Ohio has assigned the task of working out a plan that will accelerate the development of motor truck transportation.

Horace N. Trumbull, advertising manager of the S. K. F. Ball Bearing Co., Hartford, Conn., has entered the reserve officers' training camp at New Haven, Conn.

#### Sweeney Goes to Firestone

DETROIT, Oct. 5—J. B. Sweeney, formerly assistant advertising manager of the Paige-Detroit Motor Car Co., has joined the advertising department of the Firestone Tire & Rubber Co., Akron.

H. H. Shuart, manager of the Detroit Automobile Dealers Association, which suspended its activities as a patriotic measure, has become associated with the executive staff of the Denby Motor Truck Co., Detroit.

John Squires, formerly chief engineer of the Signal Motor Truck Co., Detroit, has been made chief of the Materials Division of the Denby Motor Truck Co., Detroit.

#### Chicago May Embargo L. C. L. Freight

CHICAGO, Oct. 7.—Possibility of an embargo by the railroads on all less than carload shipments of freight within a radius of 100 miles of Chicago this winter is indicated in a letter sent out by the Chicago Association of Commerce to its members with the questionnaire designed to determine to what extent motor transport lines and the return loads system can be utilized by the shippers of Chicago. The association has been requested by the State Council of Defense to assist in developing a system of highways and trolley transport within the territory tributary to Chicago, and makes the point that the moving of all possible freight over the highways by motor trucks and on trolley lines is a wartime need and a patriotic duty.

Whether or not the suggested embargo by the railroads goes into effect, the State Council of Defense expects to be in a position to handle all l. c. l. shipments within a radius of 100 miles of the city according to the letter of the Association of Commerce. The important thing necessary at this time is co-operation by the shippers.

#### License Pyrites from Spain

WASHINGTON, Oct. 8.—The War Trade Board will authorize licenses for the importation of 56,400 tons of pyrites from Spain for the remainder of the calendar year. Original regulations restricted imports of 125,000 tons up to October 1, 1918, but since licenses have not been issued for the full amount the Board has arranged to allow the 56,400 tons to enter during the last months of the year.

## Air Cleaners at Twin City S. A. E.

Gravity and Liquid Types Compared—Their Efficiency Nearly Equal

MINNEAPOLIS, MINN., Oct. 3—Water or liquid types of air washers for carbureters were said to be little more than 2 to 3 per cent more efficient than centrifugal or gravity types by C. W. Clark at the opening meeting of the S. A. E. here to-night. Mr. Clark who is engineer of the Wilcox-Bennett Carburetor Co., declared that if the truth were known quite a percentage of the water used in liquid cleaners goes to keeping down the temperature of the explosive mixture, thereby assisting in the burning of fuel and he intimated that in some cases this was the reason for using a liquid type as compared with a gravity type. There is only one kind of dust which the gravity type does not handle efficiently or on 100 per cent basis and that is the fine lava ash or dust which is encountered in some of the western areas.

In his address on air cleaners Mr. Clark classified them into four divisions, namely, cloth cleaners, gravity cleaners, liquid cleaners, and inertia cleaners.

Mr. Clark said that if the correct size cleaner is utilized the power loss is negligible or in a 40 hp. motor one-tenth horsepower. If the carbureter is cut down to suit the change in gas mixture there is no trouble. Water cleaners take little power to keep the water whirling. A manometer shows only little difference between wet and dry cleaners in amount of power required.

The speaker had not tried a cleaner with a two-cycle engine, but it would make no difference from use with a four cycle. It made no difference whether the air was hot or cold. He contemplates trying oil or kerosene, but has not yet. He said also that there is no difference whether a one-cylinder or six-cylinder engine is utilized with a water cleaner, if it is made big enough so that with the one-cylinder it will not gulp the water. If a wave motion is started water is likely to get through. Speed of the water in the cleaner has not been ascertained nor how near it comes to the velocity of the air, but it is practically still at the point of the funnel. It is not expected to be run at more than 4500 feet a minute.

### Ration Gasoline; Abolish "Gasless" Sundays

WASHINGTON, D. C., Oct. 10—Gasolineless Sundays will be abolished within the next 2 or 3 weeks and a new gasoline conservation plan adopted. The new plan probably will include a voluntary rationing of weekly gasoline consumption by motorists. Pledges will be requested. An educational campaign will accompany this pledge system.

Although there has been a weekly saving of 150,000 bbl. through the gasoline-

less Sundays there has been no appreciable surplus of gasoline accruing on the Atlantic Seaboard, according to the Fuel Administration, and although more than 500,000 bbl. of gasoline have been sent to France for war uses through the voluntary conservation, a safe margin of reserve has not yet been established here or abroad.

At one time during the recent offensive it is said that there was but 9 days supply of gasoline in France. The Liberty twelve airplane engine consumption of 35 gals. of gasoline a hour, making a squadron consumption of 1575 gals. of gasoline for an average flight, combined with the heavy demand for gasoline for trucks, tanks, and other motor vehicles, created the original shortage.

The War Department, as a result, insisted upon maintaining more than 600,000 bbl. of gasoline on the Atlantic seaboard, and as this stock during the present season and up to the gasolineless Sundays at no time amounted to 650,000 bbl. the margin for domestic use was small.

### 5000 Trucks to France in September

WASHINGTON, D. C., Oct. 10—Five thousand motor trucks were shipped to France during September according to a statement by Acting Secretary of War Crowell. Practically all of these were knocked down, although some were carried on deck.

### Chalmers Investigates Draft Questions

WASHINGTON, D. C., Oct. 10—Hugh Chalmers is in Washington conferring with Provost Marshall Crowder relative to the operation of the draft and its effect on the automobile industry and also as regards the filing of affidavits with the questionnaire by automobile manufacturers. He will secure decisions on these matters in a few days and announce them to the industry.

### Overland-Moline Exchange Basis

NEW YORK, Oct. 9—The basis on which Willys-Overland, Inc., obtained control of the Moline Plow Co. has been made public by President G. A. Stephens of the latter company. Holders of Moline common stock are given the opportunity of exchanging it at 150 per cent per share, on a par value of \$100 for 7 per cent preferred stock in the following companies: Willys-Overland, 55 per cent; Electric Auto-Lite Corp., 30 per cent. Curtiss Aeroplane & Motor Corp., 15 per cent.

Under this plan a holder of 100 shares of Moline common aggregating a par value of \$10,000, would receive stock in the other companies aggregating a par value of \$15,000 as follows:

	Par Value
82½ shares Overland.....	\$8,250
45 shares Elec. Auto-Lite.....	4,500
22½ shares Curtiss.....	2,250
Total .....	\$15,000

The comptroller of the Moline Plow Co., which has been acquired by the Willys-Overland Co., has submitted to stockholders of the first named company

## Motor Transport Has New Insignia

Helmet and Wheel for Officers and Men—Corps to Have Regular Infantry Drills

WASHINGTON, Oct. 8—The Motor Transport Corps recently organized under Brig. Gen. C. B. Drake, which controls the operations, maintenance, engineering and technical supervision of the motorized vehicles of the army, has a new insignia. This corps is now a separate division of the army.

The insignia for the officers is an emblem 1¼ in. in diameter with an automobile wheel with a pneumatic tire and the service helmet with the wings of Mercury attached. The insignia for the enlisted men is 1¼ in. in diameter and is a motor truck wheel with a solid tire. The service helmet is in the center with the wings of Mercury attached. The insignia for the officers is composed of bronze and silver. The enlisted men's insignia is entirely of bronze.

The Motor Transport Corps is now arranging to give a certain amount of infantry drill to both the officers and enlisted men, designed to enable the men to enter into the fight at any time this is necessary in the course of their service abroad. Plans are also arranged for the equipment of all the trucks with machine guns so that they will form independent machine gun units in case of need and furthermore will be protected against enemy airplanes which frequently destroy trucks by dropping bombs.

The Motor Transport Corps is greatly in need of both enlisted men and officers. This division of the army, which is new, will require from 200,000 to 250,000 men within the next year with proportionate number of officers. Opportunities for promotion are considered excellent because of the expected growth of the division. Preference for service in the Motor Transport Corps can be stated in the questionnaire filled in by men eligible for the draft and those in deferred classifications may ask to be inducted in the Corps for service. In either case the recruit can also make application to enter an officers' training camp.

the following condensed balance sheets as of July 31, 1918, of companies in which the Willys-Overland Co. is interested and other information:

Willys-Overland and subsidiary companies:  
Assets—Fixed assets \$32,027,662, investments and advances \$12,270,264, inventories receivables, etc., \$38,687,463, cash \$16,154,156, deferred charges \$387,811, good will \$14,059,932; total \$113,587,288.

Liabilities—Mortgages \$169,000, current liabilities \$27,765,267, preferred stocks, \$17,334,300, common stock and scrip \$39,416,285, surplus and reserves \$28,902,436; total \$113,587,288.

Electric Auto-Lite Corp.: Fixed assets \$1,327,922, investments \$12,231,166, current assets \$7,072,869, deferred charges \$13,607; total \$20,645,564.

## AUTOMOBILE SHEET PRICES

(Based on No. 22 Gage. Other gages at usual differentials)

	Primes only Per 100 lbs.	Primes when seconds up to 15 per cent are taken Per 100 lbs.
Automobile body stock.....	\$5.95	\$5.85
Automobile body stock, deep stamping.....	6.20	6.10
Automobile body stock, extra deep stamping .....	6.45	6.35
Hood, flat fender, door and apron, or splash guard stock.....	6.05	5.95
Crown fender, cowl and radiator casing, deep stamping.....	6.30	6.20
Crown fender, cowl and radiator casing, extra deep stamping.....	6.55	6.45
<b>Automobile Sheet Extras for Extreme Widths:</b>		
Nos. 17 and 18 over 36 in. to 44 in., 10c. per 100 lb.		
Nos. 19 and 21 over 36 in. to 44 in., 30c. per 100 lb.		
Nos. 22 to 24 over 26 in. to 40 in., 40c. per 100 lb.		
Nos. 22 to 24 over 40 in. to 44 in., 80c. per 100 lb.		
<b>Black Sheet Extras to Apply to Narrow Widths:</b>		
Oiling, 10c. per 100 lb.		
Patent leveling, 25c. per 100 lb.		
Resquaring, 5 per cent of gage price after quality, finish and size extras have been added.		
Seconds 10 per cent less than the invoice Pittsburgh price for corresponding primes.		

## Surplus Stocks Aid Tractor Men

NEW YORK, Oct. 10.—Tractor manufacturers are not all as yet definitely decided in their own minds as to just how the 25 per cent reduction in pig iron and steel for 1919 as compared with 1918 as requested by the War Industries Board is going to affect next year's production. In general, the result is going to be a reduction in the number of tractors produced by the majority of the concerns. There are some tractor manufacturers building heavy type tractors pulling ten and twelve plows and also building smaller types and in some cases the number of heavy type machines will be reduced and the pig iron and steel tonnage used in the lighter type, thereby increasing the numerical production of tractors.

There is little possibility for any of the tractor companies making very serious reductions in the amount of steel or pig iron used in their machines due to questions and design as it would call for a change in design which would delay production. Many of the large producers consequently state they will make no

attempt to redesign in order to reduce weight and keep up numerical production other than the refinements that are being carried through from time to time.

Some manufacturers are particularly fortunate in that they have a pretty heavy surplus inventory on hand as of Oct. 1, 1918, and as the ruling of the War Industries Board permits the manufacturer to work up this surplus in addition to his 1919 allotment those companies well fitted by way of inventories will not suffer so severely next year as they otherwise would.

Among all of the tractor manufacturers there is a very commendable spirit not to criticize the War Industries Board in any of its decisions but rather to be good soldiers and carry out the spirit of the ruling. At the same time there seems to be an underlying sentiment that greater farm cultivation is necessary which must be accomplished with reduced farm help and the tractor is one of the satisfactory and efficient means of making up for a reduction in help. The order or request came as a very great surprise to many of

the makers when the announcement was first made, but the ruling admitting of absorbing inventories on hand as of Oct. 1, has changed the situation to quite an extent as several tractor manufacturers were well stocked up with materials at that time which will go far to making it possible for them to maintain their 1919 production on a par and in some cases perhaps a little in advance of the 1918 schedule.

## Limit Imports of Varnish Gums

WASHINGTON, Oct. 8.—Hereafter varnish gums can only be imported into the United States if they have been shipped from abroad prior to Oct. 10, 1918, if for use for the United States Government, if from Mexico or Canada, if as returned cargo from Europe or Mediterranean Africa when the loading can be done without delay, if Manila gum from the Philippine Islands and if Kauri gum not to exceed 3,000,000 lbs. for the present calendar year. Varnish gums other than the above are banned for importation.

**A New Custom-Built Passenger Car**

NEW YORK, Oct. 8—The Automobile & Machinery Eng. Co., with offices at 1 East 42nd Street, and factory at Long Island City, is building a passenger car, designed by Otto R. Bieler, M. E., for customers who desire individuality, special body work, etc. The new car is built of standard parts, a Buda engine being used. Chassis weight is given as being 1900 lb., chassis price is \$2,700. The transmission is of four speed type, direct on third, and a special feature of the front fenders is that they turn from side to side with the wheels. Both front and rear fenders are attached to the axles. Owing to the difficulty in obtaining material, business is not being pushed at the present time, although several cars have been built and a number are on order. Plans are being made for extension as soon as conditions alter.

**Central Machine & Tool on War Work**

TOLEDO, Oct. 2—The Central Machine & Tool Co. is in quantity production on war contracts, furnishing war plants with jigs, dies, snap and tolerance gages and special machinery for war work. The company is now filling an order for special polishing machinery for a shell plant. It also makes testing machines for shells and dies and reamers for shell cases.

**Mason Tire to Make U. S. Raincoats**

KENT, OHIO, Oct. 5—The Mason Tire & Rubber Co. has closed a contract with the U. S. Army to manufacture rubberized raincoats. It is stated that quantity production was started Oct. 1. Additional plant capacity has been leased in Kent for the duration of the war. The company expects to be turning out 1,000 coats a day by the first of the year. If this production is reached the volume of business from this source will practically equal the company's total sales of tires and tubes during the 1917-1918 fiscal year ending Oct. 31.

**Square Turn Moves to Norfolk, Neb.**

CHICAGO, Oct. 4—The Square Turn Tractor Co. has removed its executive offices from Chicago to its factory in Norfolk, Neb. Several new buildings will be erected.

**More Room for Oakes**

INDIANAPOLIS, Oct. 4—The Oakes Co. is making a large addition to its factory.

**Air-O-Flex Transfers Offices**

DETROIT, Oct. 5—The Air-O-Flex Automobile Corp. has moved its offices from 570 Penobscot building to its factory at 519 Hillger Avenue.

**D'Arcy Spring Co. on War Work**

KALAMAZOO, Oct. 4—The D'Arcy Spring Co., manufacturer of seat or upholstery springs, is at present on about 80 per cent war work and will soon be on

## Current News of Factories

*Notes of New Plants—Old  
Ones Enlarged*

100 per cent basis. The company is now producing springs for Colt revolvers, springs for Browning machine guns, springs for motorcycles, springs for bayonets, springs for ambulances, and other war products. The concern is delivering thousands of springs daily and has been notified that production must be increased immediately.

**Beaudette to Manufacture Transport Bodies**

PONTIAC, MICH., Oct. 5—The O. J. Beaudette Co., manufacturer of metal automobile bodies, has been awarded large Government orders for two types of transport bodies and for a touring car body, which will insure ample work in all departments in the very near future. The plant has been operating with only a small force for several weeks past owing to curtailment of automobile production.

**Andis Tool Co. Organized**

RACINE, Oct. 5—The Andis Tool Co. has been organized with a capital stock of \$25,000 to engage in the manufacture of tools, dies, jigs, machinery, etc. The incorporators are Mathew Andis, John Oster, Frank Bichalm and Henry E. Meltzer.

**Oshkosh Mfg. Co. Builds Addition**

OSHKOSH, Oct. 5—The Oshkosh Mfg. Co., maker of tools, dies and mechanical appliances, is building a one and two-story shop addition, 40 x 100 ft., to provide much-needed facilities for handling direct and indirect Government work.

**King to Make Kitchen Trailers**

DETROIT, Oct. 4—Production on the two-wheeled kitchen trailers for the government will be started by the King Motor Car Co. about the middle of October. The company has received an order for 3000.

**Dividends Declared**

The Willys-Overland Co., Toledo, has declared the regular quarterly dividend of 25 cents on common stock, payable Nov. 1 to stockholders of record Oct. 21.

Pierce-Arrow Motor Car Co., regular quarterly dividend, \$1.25 a share, payable Nov. 1 to stockholders of record Oct. 15.

General Motors Corp., regular quarterly dividend, \$3 a share on common and \$1.50 on preferred, payable Nov. 1 to stockholders of record on Oct. 18.

**Gearshift Company Completes New Plant**

EAU CLAIRE, WIS., Oct. 5—The United States Gear Shift Co., Eau Claire, Wis., has completed its new manufacturing plant, four stories high, and 80 x 100 ft., equipped for the manufacture of the Laursen hydraulic gear-shifting device for motor vehicles. The production of gearshifts, however, will be made subservient to a large Government contract for seven different parts for coast defense and battleship gun mounts. Work on the contract will begin at once.

**Victor Rubber Co. Adds to Factory**

SPRINGFIELD, OHIO, Oct. 5—The Victor Rubber Co. has completed a large two-story tile and concrete addition to its factory. This will be devoted entirely to the production of tires. It is being equipped with modern machinery in readiness for additional manufacture.

**Killen-Straight Co. in Receiver's Hands**

APPLETON, WIS., Oct. 5—The Killen-Straight Tractor Co. has been placed in charge of C. L. Marston of that city as receiver, upon petition of a committee of creditors. The receivership is instituted to conserve the assets and maintain the company as a going concern. Lack of adequate working capital has handicapped the company in its tractor manufacturing program, but arrangements are now being made to continue the business on a broader scale than heretofore.

**Rainbow Oil Co. Incorporates**

MILWAUKEE, WIS., Oct. 5—The Rainbow Oil Co., Milwaukee, has been incorporated with a capital stock of \$30,000 to establish and maintain oil wells, refineries, etc. The incorporators are John Borman, Bert Schroeder and Andrew Benzinger.

**Acheson Oildag to Double Output**

PORT HURON, MICH., Oct. 4—The Acheson Oildag Co. is increasing its output and will double its capacity. The new equipment will cost when completed in the neighborhood of \$30,000.

**Northern Foundry Co. Doubles Capacity**

MARINETTE, WIS., Oct. 5—The Northern Foundry Co., established last fall to manufacture automotive castings, will double the capacity of its plant at once. A complete pattern manufacturing department also is being established and the business and equipment of the Dost Pattern Works, Menominee, has been purchased for this purpose. Bruno E. Dost, proprietor of the concern, has joined the Northern company as pattern works manager. Work on a new cupola, core-room addition and other buildings is now being hastened to completion. The company specializes in tractor and gas engine castings.

**Champion Ignition Co. Enlarges Plant**

FLINT, MICH., Oct. 4—The Champion Ignition Co. has let a contract for the erection of a three-story addition to its plant to cost approximately \$50,000.

## Airplane Expenses 4 Cents a Mile

Mileage Rate Same as for Dog Sleds, Prairie Schooners and Buffalo Carts

WASHINGTON, Oct. 5—In a recent opinion from the office of the Judge Advocate General, officers traveling by Government airplane may draw expenses at the rate of 4 cents a mile, which is the rate of mileage allowed where the Government furnishes transportation by prairie schooners, dog sleds in Alaska, and buffalo carts in the Philippines. The allowance for travel on trains is generally 7 cents a mile. The distinction is made, not because airplanes are less modern than trains and therefore classed with dog sleds or prairie schooners, but because customarily there are only two methods of transportation used in the service, "train" or "otherwise." Airplanes fall in the latter class.

This decision settles a doubt raised in a former opinion that because the airplanes as used in military service were not vehicles, but instruments of war, there was no authority for the payment of individual expenses of those using them for travel. Major General William L. Kenly, Director of Military Aeronautics, made the point that although airplanes are employed for combat and other war purposes, the use of the airplane in the army as a means of conveyance was of constantly increasing importance.

He maintained that this use was two-fold—first in the theater of operations, in connection with troops; second, outside the theater of operations, in the transportation of officers traveling without troops, on permanent change of station or temporary duty. In the first case, travel would be performed by airplane as it would be by horse, automobile, or other means, and no mileage would accrue. In the second case, travel would be performed by airplane in lieu of railway, and mileage, at 4 cents a mile, should be allowed.

The chief reason for such travel, as maintained by General Kenly, was its expediency. When airplanes were available, he believed, they should be used, if only for the sake of practice. There would be no additional expense to the Government in using available airplanes for travel, he held, nor any diversion of the time of pilots from their duty. At the same time travel could be accomplished far more quickly than by train, even on short trips, whether for change of station, temporary duty or purposes of inspection. If no mileage was to be drawn for such travel, officers would themselves have to bear the expenses, and if, for this reason, they avoided travel by airplane, the result in the long run would be loss of time and loss of opportunity for the full development of the use of the airplane.

The point was also made that there

was no requirement known where travel must actually be performed by railway to entitle an officer to mileage, and examples were cited to the contrary, found in the Alaskan, Philippine, and Western Service, where, when railroads were not available, mileage had been granted for travel performed by other means of conveyance.

### Cars Increase in Australia

SYDNEY, AUSTRALIA, Sept. 10—Official figures on the registration of automobiles in New South Wales for the first 6 months of 1918 show a total increase in passenger cars in use in the country of 2557 on June 30, 1918, as compared with June 30, 1917. There were registered during the first half of 1918, 1956 new cars. There has been a slight increase in the number of motor trucks in use this year as compared with a year ago. In motorcycles the registration figures show an increase of 185 during the same period. The official figures are:

	First Half Year 1917	First Half Year 1918
New registration cars....	2,556	1,956
New registration commercial vehicles.....	209	214
New Registration motorcycles .....	1,062	1,247
	On June 30, 1917	On June 30, 1918
Total cars in use in N. S. W.....	16,062	18,619
Total motorcycles in use in N. S. W.....	7,526	8,471

### Lexington Line Revised

CONNEERSVILLE, IND., Oct. 7—The Lexington Motors Co. will continue its present model with a number of modifications and improvements in the body. The radiator and cowl have been raised, the top has been redesigned, the seats have been built into the body sides and have deeper upholstery. New prices are: Seven-passenger, \$1,785; 5-passenger tourabout, \$1,685; 5-passenger convertible sedan, \$1,985; 3-passenger coupelet, \$2,450; 4-passenger sedanet, \$2,550; 4-passenger coupe, \$2,650; salon sedan, \$2,750; 5-passenger limousine brougham, \$3,250. The chassis remains unchanged.

### Operate Pending Application Approval

WASHINGTON, Oct. 3—Under the recent Presidential proclamation announced in an earlier issue, concerns engaged in importing, manufacturing, distributing and transporting crude oil, fuel oil, kerosene, gasoline and natural gas were required to secure a license from the United States Fuel Administration before Oct. 1, 1918. In those cases where the application for the license has been promptly made, the applicant can continue his business pending final action upon his application.

### Food Trucks Are Essential

WASHINGTON, Oct. 7—Motor trucks used to relieve railroad congestion by interurban transportation of food and other essential war products will be considered as in essential work and the men employed on them will be regarded as essential by the United States Employment Service.

## Air Service Clubs Organized

Standards and Traditions to Be Established to Promote Efficiency

WASHINGTON, Oct. 3—The Air Service Clubs Association has been organized following a meeting here of 800 officers of the Army Air Service yesterday. The purpose of the association is to establish standards and traditions and promote the efficiency of the Air Service, disseminate professional knowledge and provide means for social activities at all places where members are stationed. The Association will include all of the local air service clubs which have been organized at various flying fields and training stations.

At the meeting yesterday Major General William L. Kenly, Chief of the Division of Military Aeronautics, presided. Following the adoption of the constitution, officers were elected as follows:

Major General Wm. L. Kenly, President; W. C. Potter, 1st vice-president; Col. G. C. Drant, 2nd vice-president; Col. M. F. Davis, 3d vice-president; Major Maxwell Kirby, 4th vice-president; Col. G. C. Edgar, treasurer; Lt. Colonel H. S. Brown, assistant treasurer; Captain John H. Packard, secretary, and 1st Lieutenant Tom Poe, assistant secretary. John D. Ryan, Assistant Secretary of War, was elected chairman of the Board of Control, and the following were elected members of the Board of Control: Col. H. H. Arnold, Col. W. E. Gilmore, Col. C. A. Seonne and A. A. Landan, for one year; Col. Arthur Woods, Col. F. R. Kenney, Col. G. H. Crabtree and C. W. Nash, for two years; and Col. A. L. Fuller, Lt. Col. B. F. Castle, Lt. Col. Milard F. Harman, Jr., and Major Wm. R. Malone, for three years.

It is the purpose of the Air Service Clubs Association to issue a magazine periodically and to organize clubs at all Air Service flying fields and stations.

### Tire Filler Makers Organize

CHICAGO, Oct. 7—An association styled American Tire Filler Industry was formally launched here following a conference of the principal manufacturers of tire filling compounds. The following officers and directors were elected: President, Franc D. Mayer, Essenkay Products, Chicago; first vice-president, Frank A. Hager, Universal Tire Filler Co., Portland, Ore.; second vice-president, Lee W. Lockwood, Dahl Punctureless Filler & Rim Co., Minneapolis; third vice-president, W. W. Major, National Rubber Filler Co., Midlothian, Tex.; secretary, C. P. Umstot, Peerless Tire Filler Co., Chicago; treasurer, L. G. Harris, Wolverine Tire Cushion & Accessory Co., Detroit; directors, J. Wolff, National Synthetic Tire & Rubber Co., New York, and C. G. Schwarz, Panama Rubber & Equipment Co., St. Louis.

## Aircraft Production Contracts

WASHINGTON, Oct. 2—Following is a list of contracts placed by the Bureau of Aircraft Production:

Dayton Engineering Laboratories Co., Dayton, spare ignition parts.  
Champion Ignition Co., Flint, spark plugs.  
Empire Axle Co., Dunkirk, N. Y., engine spares.  
Durke & James, Inc., 240-258 East Ontario Street, Chicago, Ill., cameras.  
Wright-Martin Aircraft Corp., New Brunswick, engine spares.  
Wright-Martin Aircraft Corp., New Brunswick, engine spares.  
Central Dry Plate Co., St. Louis, photographic dry plates.  
English & Mersick & Co., New Haven, radiators and attachments.  
The General Rubber Goods Co., Cleveland, shock absorber cord.  
Ohio Rubber Co., Cleveland, shock absorber cord.  
Baker & Lockwood Manufacturing Co., Kansas City, services coloring airplane hanger tents.  
Eastman Kodak Co., Rochester, aerial cameras.  
Astoria Veneer Mills & Dock Co., New York, lumber.  
English & Mersick Co., New Haven, spares, radiators and attachments.  
Ohio Rubber Co., Cleveland, shock absorber cord.  
Stone Propeller Co., Dayton, propellers.  
Starr Plano Co., Richmond, propellers.  
Giant Furniture Co., High Point, propellers.  
Hallet & Davis Plano Co., Boston, propellers.  
Brewster & Co., Long Island City, propellers.  
Flottorp Manufacturing Co., Chicago, propellers.  
Curtiss Aeroplane & Motor Corp., Buffalo, propellers.  
A. C. Clark & Co., Chicago, oxygen apparatus repairs.  
Claphone Co., Akron, claraphone tubes.  
International Duplex oat Co., New York, furlined suits.  
Brown Instrument Co., Philadelphia, thermometers.  
Eastman Kodak Co. of New Jersey, Rochester, photographic supplies.  
Eastman Kodak Co. of New Jersey, Rochester, cameras, carrying cases and repair kits.  
Positype Co., Cleveland, bromotype paper.  
J. J. O'Connor, Jersey City, steel drums.  
California Burdett Oxygen Co., Oakland, hydrogen gas.  
Berger Mfg. Co., Canton, material for hangars.  
Sayles Finishing Plant, Saylesville, services, inspecting balloon cloth.  
Ideal Veneer Lumber Co., Franklin, lumber.  
Wood-Mosaic Co., New Albany, lumber.  
Standard Aircraft Corporation, Elizabeth, steel tubing.  
John A. Roebling's Sons Co., Trenton, aviator cord.  
Scheuerman Co., Inc., 332 Pearl Street, Buffalo, pilot's safety belts.  
Robbins & Meyers Co., Springfield, electric generators.  
North East Electric Co., Rochester, electric generators.  
Kunhardt & Co., New York, castor beans.  
Commercial Bank of Spanish America, Ltd., New York, castor beans.  
C. L. Van Doren, Gloversville, flying gloves.  
Wright-Martin Aircraft Corp., New Brunswick, engine spares.  
Wright-Martin Aircraft Corp., New Brunswick, engine spares.  
Positype Co., Cleveland, bromotype paper.  
Clifton Mfg. Co., Jamaica Plain, friction tape.  
Burke & James, Chicago, chemicals.  
Pittsburgh Steel Products Co., Pittsburgh, seamless steel tubing.  
Pittsburgh Steel Products Co., Pittsburgh, seamless steel tubing.  
Studebaker Corporation, Detroit, forgings for cam shaft.  
Interstate Machine Products Co., Rochester, intake pipe for engine.

## Contracts

Interstate Machine Products Co., Rochester, intake rocker arms.  
Hess Bright Mfg. Co., Philadelphia, crank case thrust bearings.  
Taylor Instrument Co., Washington, airplane inclinometers.  
Taylor Instrument Co., Washington, compasses.  
Erie Specialty Co., New York City, spares for planes.  
John A. Roebling's Sons Co., Trenton, wire.  
John A. Roebling's Sons Co., Trenton, wire.  
Erie Specialty Co., New York, spares for planes.  
Samuel J. Shimer & Sons, Milton, engine spares.  
Samuel J. Shimer & Sons, Milton, engine spares.  
Wolverine Brass Works, Grand Rapids, gear repairs.

## Engineer Depot Orders

WASHINGTON, Sept. 26—Following is a list of orders placed by the General Engineer Depot of the Army:

Hercules Gas Engine Co., Evansville, Ind., gasoline engines.  
Republic Rubber Co., Washington, red sheet gasket packing.  
Cook Motor Co., Delaware, Ohio, gasoline engines.  
Tucker City Rubber Co., Philadelphia, rubber gaskets.  
Quaker City Rubber Co., Philadelphia, rubber gaskets.  
General Electric Co., Schenectady, parts for searchlights.  
International Motor Co., Washington, steel dump bodies.  
Empire Rubber & Tire Co., Trenton, rubber-lined hose.

## Dealers May Get War Work

WASHINGTON, D. C., Oct. 7—Dealers who have facilities for doing war work may secure war work, according to an official announcement, according to their facilities for manufacturing or assembling, and the facilities of many dealers are mostly bare floor space. The announcement is made by C. A. Otis, chairman of the Committee on Resources and Conversion, War Industries Board, who states that dealers may be able to effect progress in this direction by combining their organizations. As was announced some time ago, this committee was organized with 20 industrial zones, each in charge of a regional adviser, and sub-zones in charge of sub-regional advisers. Dealers who wish to investigate this work are requested to write to Chairman Otis, who will put the dealers in touch with the sub-regional adviser, who will give the dealers all the necessary information.

## Ordnance Department Contracts

WASHINGTON, Oct. 4—The following contracts have been placed by the Ordnance Department of the United States Army:

Maxwell Motor Co., Detroit, and Minneapolis Steel & Machinery Co., Minneapolis, test tools.  
Nash Motors Co., Kenosha, steering knuckles, spindle washers and brake linings.  
Four Wheel Drive Auto Co., Clintonville, miscellaneous truck equipment.  
Holt Mfg. Co., Peoria, gaskets and equalizing rockers.  
Nash Motors Co., Kenosha, truck spare parts.  
Cleveland Twist Drill Co., Cleveland, drilling and countersinking high-speed steel.  
C. A. Shaler Co., Waupun, vulcanizing material.  
Standard Oil Co., New York, wicks.  
North & Judd Mfg. Co., New Britain, and O. B. North & Co., New Haven, roller buckles.  
United Motors Corp., Harrison, steel cores.  
Allen Motor Car Co., Fostoria, recoil spring adjusters.  
Dodge Bros., Detroit, repair tools.  
Taft-Pierce Mfg. Co., Woonsocket, musketry rules.  
Gray & Davis Co., Boston, fuses.  
Federal Pressed Steel Co., Milwaukee, and Pressed Steel Tank Co., Milwaukee, Livens gas shells.  
The Nash Motors Co., Kenosha, motor parts.

## Engineer Depot Orders

WASHINGTON, Oct. 4—The following contracts have been placed by the General Engineer Depot of the Army:

The B. F. Goodrich Rubber Co., Akron, hose.  
Willard Storage Battery Co., Cleveland, batteries.  
The Buda Co., Chicago, track drills.  
Empire Tire & Rubber Corp., Trenton, fire hose.  
Empire Tire & Rubber Corp., Trenton, fire hose, rubber lined.  
The Buda Co., Washington, jacks.  
General Electric Co., Schenectady, lamp switches.  
The Winton Co., Cleveland, parts for generating set.  
Metal & Thermit Corp., New York, thermit and ignition powder.  
Dayton Rubber Mfg. Co., Dayton, Ohio, airless tires.  
Eiseman Magneto Co., Brooklyn, round carbons.  
Studebaker Corp., South Bend, log wagons.  
Ford Motor Co., Detroit, searchlight parts.

## Republic Earns \$300,564 in July

NEW YORK, Oct. 7—During the month of July the Republic Rubber Co., Youngstown, Ohio, earned net profits of \$300,564. During the three months ended July 31, sales amounted to \$7,598,536 and earnings in the same period were \$574,013. August sales amounted to \$1,429,000.

## \$3,000,000 Addition for Holt

PEORIA, Oct. 7—The Holt Mfg. Co. has let contracts for two assembly shops 500 x 80 and three new machine shop units together with additions to its power and heating plant, the whole to amount to about \$3,000,000.

## Calendar

## ENGINEERING

Nov. 14-15 New York. Society of Naval Architects and Marine Engineers. Twenty-sixth general meeting. Engineering Societies Bldg., 29 West 39th Street.

## Master Strength Means Extra Service

Master Trucks are mighty in the full sense of the word. Every part is over-sized, built with an extra margin of safety. Hard roads and overloads have been deliberately considered in planning Master Trucks—built to be as nearly unbreakable as it is possible to build them.

Steady pulling over rough roads—enduring strains that would wreck a truck of less stamina—minimum upkeep cost and superior service—make the Master Reputation.

Master engineers have devoted years of study to the sureness of design that means perfect balance. Every part is designed for every other part—not merely for size but for *relative strength*. The result is that in all details Masters are scientifically correct in size, weight and balance.

We have built the *Best* to stand up under the *Worst*. No matter what the transportation problem—how bad the roads—how great the load strain—they are

## Master of the Load on ANY Road

Every part is strong—powerful—permanent. From Maine to California Master Trucks are making good. They are Masters in materials—design—strength.

*Until the War is won, Master Trucks will be sold for service only in essential industries as defined by the War Industries Board*

## Tractor Makers Protest Curtailment

**30 Manufacturers Form American Tractor Association and Will  
Lay Their Case Before the War Industries Board—Claim  
25% Restriction Order Jeopardizes Their Business  
and That of Parts Makers as Well**

**C**HICAGO, Oct. 11—The first example of united opposition to a ruling of the War Industries Board because of a curtailment order comes from thirty farm tractor manufacturers who see their business practically wiped out by the 25 per cent reduction ruling of the War Industries Board for 1919. These tractor manufacturers have formed themselves into a new organization known as the American Tractor Association, with the immediate object in view of laying their case before the War Industries Board and presenting to that board an analysis of conditions which these manufacturers think had something to do with the 25 per cent curtailment order.

Some of these thirty tractor manufacturers have been producing tractors in fairly good quantities for the last 2 years, yet notwithstanding this they see their business seriously threatened through the ruling of the Priorities Division of the War Industries Board. Many of these concerns have already obligated themselves with manufacturers of parts for their 1919 production and see in the recent ruling no apparent recognition that such business arrangements have already been entered into and were entered into before the hearing of the War Industries Board on the curtailment subject.

Few, if any, of these tractor manufacturers were invited to the hearing before the War Industries Board on Sept. 17 when the question of tractor curtailment was discussed. The War Industries Board at that time discussed the subject with the War Service Committee, representing the National Implement and Vehicle Association, and while the meeting was only to have been a preliminary one it resulted in the 25 per cent curtailment. There were many tractor firms not members of this association that have built thousands of tractors and who did not even know that such a meeting was taking place, and who had no voice whatever in the curtailment order. There were scores of smaller tractor concerns that have been in the development process for a year or so and were not notified of the meeting and did not directly or indirectly have a chance to protest or express their views on this subject. The whole matter was handled by the War Service Committee, which, before taking the subject up, did not call a meeting of all tractor manufacturers to discuss the subject. It was a plain case of extinction for practically all of these newcomers, who had not got far into production, without an opportunity of even voicing a protest.

The 25 per cent curtailment order has not only

jeopardized the future of these concerns, but its influence has extended to the manufacturers of parts, such as engines, gearsets, ignition, lubrication and all other parts essential for the tractor. It is, therefore, not surprising that all of these parts makers, or a great many of them, have united with the new American Tractor Association and are ready to take up the case with the War Industries Board. These parts manufacturers have large contracts for future delivery with many of these smaller tractor concerns. The great tractor demand of the present year has resulted in programs for factory enlargements, and to meet these increases in production these parts makers have become part and parcel of these newer firms in the tractor field.

### Organization Includes Tractor Pioneers

The list of thirty charter members in the American Tractor Association contains the names of manufacturers of standing, who have been manufacturing tractors for several years. The list also contains the names of parts makers of standing, so that the new organization does not represent a group of mushroom concerns that have sprung up during the past year, but rather firms that have been doing development work for several years and parts makers of long and established standing in the tractor industry. Included are manufacturers of electric apparatus, gearsets, carbureters and radiators who have established businesses, and some of them have been pioneers in the tractor industry.

The formation of the American Tractor Association comes as the result of a settled conviction in the minds of the smaller tractor manufacturers and parts makers that the War Industries Board has been influenced by the membership of the Tractor Division of the Farm Implements Committee of the National Implement and Vehicle Association, which counts in its membership the large and powerful manufacturers of tractors and farm implements and to whose advantage it would be to choke off considerable new development in tractor manufacture. Such has not been publicly stated by the new organization, but this is the sentiment of many comprising it, and it is without doubt the leading spur to organization.

Immediately the ruling of the Priorities Division of the War Industries Board with its 25 per cent restriction on the amount of iron and steel for 1919 was announced by the Farm Implements Committee, the smaller tractor manufacturers and makers of parts sensed disaster to their growing business and at once began to agitate for a modification of the ruling. Believing that they had not been adequately represented at the Washington hearing before the War Industries Board, which resulted in the ruling, and realizing that without organization any protest they might make would be ineffective, the necessary measures to bring about the American Tractor Association were taken.

As a result at the formation meeting held in Chicago Wednesday a representative committee was appointed to go to Washington and present the case of the tractor and parts manufacturers in order to se-

cure a rescinding or modification of the ruling. This committee will demand of the War Industries Board that the weaker interests of the tractor industry be given representation in order that the needs of an essential and growing industry shall receive proper recognition.

It is hinted by many of these newer tractor manufacturers that there is a very large representation of the old-time tractor interests on the War Industries Board and connected with this organization, and that the ruling savors very strongly of being a protection measure to these old-line concerns, which have resented very much in the last 2 years the entrance of new blood into the tractor field and have also strongly resented the entry of the automobile manufacturer, as well as the influence of automobile design on tractor engineering.

The opposition of many of the old-line tractor makers to the Fordson tractor has been very generally construed as not so much an attack against Henry Ford as rather a defensive act of these tractor manufacturers against the invasion of the old tractor circle of makers by the modern automobile and truck industry. It has been rather generously stated by a few of the leading old-time tractor manufacturers that Henry Ford beat them to it in the Fordson tractor, and that if they had thought of it in time they would have done the same thing, but they did not. The opposition to the Fordson started in England as soon as the Government placed tractor contracts. The scene of attack next shifted to Canada and finally to the United States, where it has continued pretty generally ever since. Fortunately there are some of the older interests and also the stronger interests among the old tractor manufacturers who have publicly stated that they will welcome everything that is good in tractor design, no matter whether it comes from the ranks of automobile manufacturers or tractor concerns. They state unequivocally that in these war days the best that comes out must be welcomed and that there must not be opposition to development of design and increase in tractor efficiency.

### Thirty Charter Members in Organization

Charter members of the American Tractor Association to the number of thirty signed the following pledge:

*We, the undersigned, tractor manufacturers and parts makers, and trade press, do subscribe as charter members to a national organization to be known as the American Tractor Association, with central office in Chicago, Ill., and pledge ourselves to the payment of the first annual dues of \$50.*

Erd Motor Co.  
Square Turn Tractor Co.  
Bullock Tractor Co.  
Reed Tractor Co.  
The Star Tractor Co.  
The Evans Mfg. Co.  
Zelle Tractor Co.  
Powell Tractor Co.  
Sumpter Div. Splitdorf Electrical Co.  
Climax Engineering Co.  
Kohl Tractor Co.  
U. S. Tractor & Machinery Co.

Parrett Tractor Co.  
Belt-Rail Tractor Co.  
Foote Bros. Gear & Machine Co.  
Wisconsin Farm Tractor Co.  
Kokomo Electric Co.  
Perfex Radiator Co.  
Brewer Mosel Automobile Co.  
Nilson Tractor Co.  
Wilcox-Bennett Carburetor Co.  
Agrimotor.  
The John Lauson Mfg. Co.  
Illinois Tractor Co.

H. C. Doman Co.  
Turner Mfg. Co.  
Aulson Tractor Co.

Geo. D. Bailey Co.  
Interstate Tractor Co.  
Hooven Radiator Co.

Officers, members of executive committee and committee chairmen of the American Tractor Association were elected as follows:

President, B. F. Sprankle, general manager Illinois Tractor Co., Bloomington, Ill.  
First Vice-President, W. N. Smith, president Monarch Tractor Co., Watertown, Wis.  
Second Vice-President, A. C. Bennett, Wilcox-Bennett Carburer Co., Minneapolis, Minn.  
Treasurer, John B. Foote, president Foote Bros. Gear & Machine Co., Chicago, Ill.  
Secretary, Henry Farrington, Agrimotor, Chicago, Ill.

#### Members of Executive Committee

C. B. Stebbins, president and general manager Climax Engineering Co., Clinton, Iowa.  
J. R. Manning, secretary Coleman Tractor Co., Kansas City, Mo.  
Edward Kohl, president Kohl Tractor Co., Cleveland, Ohio.  
J. C. Westmont, president Wisconsin Farm Tractor Co., Sauk City, Wis.  
Leonard Nilson, engineer Nilson Tractor Co., Minneapolis, Minn.  
R. F. Florian, treasurer Square Turn Tractor Co., Norfolk, Neb.  
Claire L. Barnes, vice-president and general manager Parrett Tractor Co., Chicago, Ill.

#### Chairmen of Committees

*Membership Committee*—W. A. Carrell, vice-president Erd Motor Co., Saginaw, Mich.  
*Constitution and By-laws Committee*—L. M. Turner, vice-president and general manager Turner Mfg. Co., Port Washington, Wis.  
*Investigation and Statistics Committee; Publicity Committee*—Henry Farrington, Agrimotor, Chicago, Ill.

The members of the membership committee will remain in Chicago for the remainder of the week making plans for an aggressive campaign. Already assurances have been received from a number of tractor and parts manufacturers who were not represented at the meeting that it is their intention to join. It is hoped to have the membership pass the hundred mark within thirty days.

Another meeting of the association will be called by the executive committee in the near future.

By the 25 per cent curtailment for 1919 many of the old established tractor makers have practically admitted that they will not to any extent be interfered with in 1919 production because the ruling permits them to make use of the inventory which they have had on hand as of Sept. 30, 1918. In addition to this inventory they are permitted to secure 75 per cent of the steel from Oct. 1, 1918, to Sept. 30, 1919, that they had during the previous year. In many cases the inventory on hand amounts to considerably more than the 25 per cent curtailment, so that these concerns do not face any curtailment at all. In some cases it will be possible for them to increase their numerical production.

On the other hand, the small manufacturer who has been in the development stages is apparently denied any such field of manufacture. The ruling is that if he has not built more than ten machines in the year ending Sept. 30 he cannot build more than ten during the year Oct. 1, 1918, to Sept. 30, 1919, no matter whether he has obligated himself for

the materials and apparently irrespective of any inventory he may have on hand. The ruling to such a group of manufacturers means practically business extinction.

Going a step farther, the ruling provides that those manufacturers that have not manufactured over fifty machines in the past year cannot increase this output. The unfairness of such a ruling lies in the fact that new concerns that have developed tractors and put fifty out have plans laid for manufacturing several hundred next year and have obligated themselves to the parts makers, and in many cases have inventories on hand. At the same time the parts makers have gone ahead with the purchase of materials, as well as the production of parts for these, and the ruling apparently takes no recognition of what the parts maker has done up to the present and provides no modification for these new tractor concerns and their programs.

The committee appeared to go to Washington to try for a modification of the Priorities Division ruling consists of the following members:

B. F. Sprankle,	John B. Foote,	R. K. Schreiber,
C. B. Stebbins,	C. W. Lamson,	G. E. Manning,
Edward Kohl,	C. L. Barnes,	L. M. Turner.

Following is the registration at the meeting:

W. A. Carrell, vice-president Erd Motor Co., Saginaw, Mich.  
W. E. Foster, stockholder Square Turn Tractor Co., Norfolk, Neb.  
O. C. Parker, general manager, Bullock Tractor Co., Chicago, Ill.  
E. L. Rose, sales manager Reed Tractor Co., Kalamazoo, Mich.  
C. W. Pendock, president and general manager Milwaukee Machine Tool Co., Milwaukee, Wis.  
P. D. White, vice-president and manager The Star Tractor Co., Findlay, Ohio.  
H. P. G. Coats, vice-president and manager American Engine & Tractor Co., Charles City, Iowa.  
R. T. Evans, vice-president The Evans Mfg. Co., Hudson, Ohio.  
S. W. Harger, Chicago, representing Graham Bros., Evansville, Ind.  
W. C. Zelle, president Zelle Tractor Co., St. Louis, Mo.  
F. L. Howard, chief engineer Hooven Radiator Co., Chicago, Ill.  
S. A. Witt, sales department Detroit Lubricator Co., Chicago, Ill.  
John Powell, general manager Powell Tractor Co., Elwood, Ind.  
E. P. Gould, sales engineer Sumpter Div. Splitdorf Electrical Co., Chicago, Ill.  
C. B. Stebbins, president and general manager Climax Engineering Co., Clinton, Iowa.  
Edward Kohl, president Kohl Tractor Co., Cleveland, Ohio.  
F. P. Blake, Charles F. W. Nichols Co. Adv. Agency, Chicago, Ill.  
B. F. Sprankle, general manager Illinois Tractor Co., Bloomington, Ill.  
H. D. Lauson, general manager The John Lauson Mfg. Co., New Holstein, Wis.  
E. R. Aulson, president Aulson Tractor Co., Waukegan, Ill.  
G. M. Lamson, president U. S. Tractor & Machinery Co., Chicago, Ill.  
A. X. Merz, secretary Madison-Kipp Lubricator Co., Madison, Wis.  
R. K. Schreiber, president H. C. Doman Co., Oshkosh, Wis.  
L. M. Turner, vice-president and general manager Turner Mfg. Co., Port Washington, Wis.  
H. P. Albaugh, Chicago, Ill., representing the Square Turn Tractor Co.  
W. E. Smith, president Rogers & Smith, Chicago, Ill.

# What Langley Did for the Science of Aviation

His Early Experiments in Aerodynamics at Allegheny Observatory—How He Worked Out Fundamentals and Developed Basic Principles Before Attempting to Obtain Free Flight

## PART I

**I**N order to appreciate fully the value and extent of the contributions of Samuel Pierpont Langley to the science of aerodynamics and the application of the principles of that science to practical mechanical flight, one must not only know who Langley was, but what he was, measured as a scientist and as a man.

Of all those who in the early days investigated the possibilities of flight with heavier than air machines, Langley was undoubtedly the best equipped by training, experience and natural aptitude. He was a scientist of world renown whose honors and recognition had been won by the accomplishment of things of which the value could be measured in terms of practicality. He was fitted to succeed in his efforts in aviation, and he did succeed, but the demonstration of his success came when it was too late for him to enjoy the unstained satisfaction in a realization of accomplishment which would have been the greatest reward that he, being the manner of man he was, could possibly have desired. That satisfaction was denied him largely through the attitude taken toward his invaluable work by a dim visioned public press, which was largely responsible for the cutting off of the supply of funds which would have made a continuation of his experiments possible. And the disappointment and humiliation which resulted from cruel criticism and ridicule heaped upon him and those who believed in him and supported and encouraged him in his efforts and the sad result which followed made his life the tragedy it was and him a martyr to a cause which, as we see to-day, was destined to become a vital factor in establishing the freedom of mankind.

Samuel Pierpont Langley was the descendant of a long line of substantial and intelligent citizens of New England, among whom were skilled mechanics, business men, clergymen and teachers, including a president of Harvard University. As Andrew D. White said in a memorial address at the Smithsonian Institution, "They were of those who build or enrich states by conscientious work and sane thought."

Langley was born in Roxbury, Mass., on August 2, 1834, and was educated in the schools of Boston. At 23, having been trained in architecture and civil engineering,

he went to St. Louis and Chicago, where he followed his profession for seven years. A natural fondness for astronomy then caused him to give up his profession and devote himself to the making of telescopes, refractors and a reflector. This latter period of about three years was followed by an extended visit to Europe, where he spent most of his time in observatories, scientific institutions and art galleries. Upon his return he was made, first, an assistant in the Harvard Observatory and later professor of mathematics and director of the observatory at Annapolis. At 32 he was made professor of astronomy and physics of the Western University of Pennsylvania and director of the Allegheny Observatory. He remained there for twenty years, and during the latter part of his connection conducted the experiments in aerodynamics which extended over more than three years from 1887, and of which the results are to-day counted among the most valuable contributions to the science.

It was while he was at Western University that, with his ability to

### Langley's Achievements

1—His experiments in aerodynamics conducted at Allegheny Observatory from 1887 to 1891 resulted in the compilation of data never before obtained which provided a firm basis upon which to build the science of aviation. Specifically, as summarized by Octave Chanute, they:

- (a) Established a more reliable coefficient for rectangular pressures than that of Smeaton;
- (b) Proved that upon inclined planes the air pressures were really normal to the surface;
- (c) Disproved the Newtonian law, that the normal pressure varied as the square of the angle of incidence on inclined planes;
- (d) Showed that the empirical formula of Duchemin, proposed in 1836 and ignored for fifty years, was approximately correct;
- (e) That the position of the center of pressure varied with the angle of inclination and that on planes its movements approximately followed the law formulated by Joessel;
- (f) That oblong planes, presented with their longest dimension to the line of motion, were more effective for support than when presented with their narrower side;
- (g) That planes might be superposed without loss of supporting power if spaced apart certain distances which varied with the speed;
- (h) That thin planes consumed less power for support at high speeds than at low speeds.

2—He made a steam propelled model aerodrome in 1896 which repeatedly demonstrated its ability to make long flights.

3—He built the first gasoline engine suitable for the propulsion of a man-carrying aeroplane.

4—He built the first gasoline propelled model aeroplane to make successfully a sustained free flight.

5—He built the first man-carrying aeroplane capable of sustained free flight, the successful demonstration of which remained for others to accomplish after his death.

comprehend the practical, he saw the need for a standardized time system for the operation of the railroads of the country, and not only devised the means for providing it but persuaded the railroads to adopt his plan and the method of carrying it out and to furnish the necessary equipment. He linked astronomy and railroad operation and eventually sent the time twice a day from his clock, set by the sun, to stations on railway lines extending for thousands of miles. More than any other man, he is responsible for the system of standardized time in use to-day.

Langley's investigations of the surface of the sun and his study of sun spots resulted in drawings and records which, though made before the year 1875, are still regarded as the most authoritative data available on the subject. This fact bears eloquent testimony to the infinite care and patience with which he worked and the keen intelligence which guided his efforts.

In 1879 and 1880 Langley developed and constructed the bolometer, an instrument of such infinite delicacy and precision that it indicates accurately variations in temperature of less than one-hundred thousandth of a degree centigrade. By means of it he was able to analyze in detail the heat of the moon in a lunar heat spectrum.

In 1886, following a long succession of astronomical investigations of an original and far reaching character, he was invited to become and became assistant secretary of the Smithsonian Institution with the stipulated privilege of continuing his research work at Allegheny Observatory. In August of the following year he was made secretary of the institution and held the position until his death, on February 27, 1906.

Knowing who and what Dr. Langley was gives one, as we have said, a better conception and keener appreciation of the value of his contributions to the science of aeronautics.

#### His Methods Logical and Scientific

Unlike nearly all other investigators in the field of mechanical flight, Langley did not follow the cut-and-try methods of the average experimenter. He engaged first in the most painstaking research to determine fundamentals and to discover and classify the principles involved so that he could successfully employ them later. The process which he followed was logical and scientific. It began in the laboratory and ended in the work shop. By the time that he was ready to begin to construct he knew not only what he was going to build, but how he was going to build it, and why it should be built in that particular way. He attacked the problem of developing a new science and of practically applying the principles involved in much the same manner as a naval architect would to-day lay out plans for a merchant ship, and hav-

SAMUEL PIERPONT LANGLEY

*Langley's experiments in aerodynamics resulted in the compilation of data which provided a firm basis upon which to build the science of aviation*

ing finished them, send them on to the constructors with the knowledge that if the plans laid out were followed the result expected would be accomplished. There was this difference, however, in Langley's case: He was obliged to work out the fundamentals upon which the plans for construction were based.

A close study of the work which Langley did at the Allegheny Observatory in devising instruments and apparatus for making the tests necessary for the development of the principles he sought results in unceasing wonder at and admiration of the thorough and careful manner in which he carried out his experiments even to the smallest detail. It is impressed upon one, in going over the record of these experiments, that no detail was too small to be regarded by Langley as unimportant. He seems to have given thought to everything that could possibly have been considered. He provided and made allowances for all extraneous factors and influences which could have affected the results and have

thus led him from the truth he sought.

The work of Langley in theoretical and applied aerodynamics divides itself naturally into three distinct parts:

1—His experiments in aerodynamics at Allegheny Observatory, where for three years he confined himself exclusively to the making of tests for the determination of principles and the development of data to be used later in constructing models and man-carrying machines.

2—His experiments with rubber-pull and steam-driven models, as a result of which he was able to construct a steam-propelled model which flew for more than three-quarters of a mile.

3—His work with the quarter-size gasoline engine-driven model and the construction, after its successful demonstration, of a full sized man-carrying machine propelled by a gasoline engine.

The fourth part of Langley's work, although it was concluded several years after his death, is the demonstration of the practicability of the machine he unsuccessfully attempted to fly, which was accomplished at the plant of the Curtiss Airplane & Motor Corp. at Hammondsport, N. Y., in the fall of 1914.

This article is the first of a series of four, dealing with the contributions of Dr. Langley to the science of aerodynamics, which will appear in AUTOMOTIVE INDUSTRIES. It deals only with his experiments at the Allegheny Observatory. The three remaining articles will take up the other parts of his work, as outlined above.

Langley was prompted to make his investigations into the possibilities of mechanical flight not so much by the interest which he had felt in the subject for, as he put it, as long as he could remember, as by the conflicting theories which were advanced and the evidently erroneous

explications which were offered even by some supposedly scientific thinkers. There was so much confusion about the whole subject that Langley decided to find for himself by means of laboratory experiments just what the possibilities were.

As was characteristic of him, he gave his entire self over to the undertaking and at the end of something more than three years of the closest kind of work he announced in the introduction to his "Experiments in Aerodynamics," written when the experiments were completed, that his researches had led to the conclusion "that mechanical sustentation of heavy bodies in the air, combined with very great speeds, is not only possible, but within the reach of mechanical means we actually possess, and that while these researches are not meant to demonstrate the art of guiding such heavy bodies in flight, they do show that we now have the power to sustain and propel them." This was written in 1891, many years before the demonstration of the truth of these words was accomplished.

Langley's first three years of work in aerodynamics was, it has been said, down at the Allegheny Observatory, at Allegheny, Pa., to which description of location should be added, if we are to follow the example of thoroughness which Langley set in his own description of what he did there ("lat. 40 deg. 27 min. 41.6 sec.; long. 5h. 20m. 2.93s.; height above sea level, 1145 ft.")

#### His Apparatus

His principal piece of apparatus was a large whirling table with a radius of 30 ft., which consisted of two symmetrical wooden arms revolving in a plane 8 ft. above the ground. It was driven by a gas engine of  $1\frac{1}{2}$  horsepower during the early days of experimenting, but as this was found to be inadequate for the work a steam engine of 10 horsepower was substituted later. A belt from the engine connected with a set of step pulleys providing four different rates of speed. These pulleys in turn drove a horizontal shaft which ran under ground to the axis of the whirling table and drove the latter by means of a pair of bevel gears, having a ratio of 1 to 5. The step pulleys gave 25, 50, 100 and 200 revolutions to the whirling table for 1000 revolutions of the engine.

During the last of his experiments the gear ratio of the bevels was changed to 1 to 4 and a new system of

pulleys was installed so that at 120 revolutions of the engine per minute, 48, 24 and 12 revolutions of the whirling table per minute were secured and these corresponded with 100, 50 and 25 miles per hour at the end of the arms.

It was possible, of course, to secure any intermediate speed by varying the speed of the engine.

Langley did not leave the determination of the actual speed at the end of the arm at any time to a calculation of the speed of the engine at that moment and the gear ratio employed. The precise velocity was obtained by means of an electrical registration on a chronograph placed in the observatory. Four equally spaced contact pieces were secured to the fixed axis of the table and a moving contact piece was secured to a horizontal arm screwed into the axis of the turntable and revolving with it.

#### Advised Erection of Whirling Table Indoors

The whirling table was located in the open air because it was not practical to construct a large building to house it. Langley felt, also, that it was better to conduct his experiments in the open air on calm days, as "in a confined building the rotating arm itself puts all the air in the room into slow movement, besides creating eddies which do not promptly dissipate." It turned out, however, that calm days were not so numerous as had been expected, and in his record of what transpired Langley complained that "from the beginning to the end of the experiments the presence of wind currents continued to be a source of delay beyond all anticipation as well as of frequent failure," and he advised any one making similar experiments to erect his whirling table in a large building.

For use in connection with the whirling table Langley devised and constructed a large number of special instruments, each designed to establish some particular fundamental. Many of these instruments will be described and illustrated later. The care with which the details of this apparatus were worked out is little short of amazing. The results of his long investigations are summarized at the early part of this article and constitute, as is now generally acknowledged, probably the most substantial contributions to the science that any one man has made. *(To be continued)*

## Airplane Altitude Record Now 28,900 Ft.

**C** LIMBING over 5 miles into the air, to an altitude of 28,900 ft., and coming down to a site 200 miles distant from the starting point, were some of the extraordinary experiences of Capt. R. W. Schroeder, Air Service, U. S. A., on Sept. 18. Capt. Schroeder's altitude record has been officially confirmed. He started his flight at Dayton and landed at Canton, Ohio. In the report of the climb, filed with Major General Kenly, Director of Military Aeronautics, he said:

"In order to take an airplane to a higher altitude than any other pilot in the world, I found that it would require more than one or two attempts. I made three attempts. The first one took me to 24,000 ft., the second to 27,000 ft. and the last one to 28,900 ft., but now I feel certain that I can get to 30,000 ft.

"The cold thin air is one's greatest adversary. First of all, one must make a study of the performance of his motor at these high altitudes. I took off at 1.45 p. m. Wednesday, Sept. 18, and made a steady circular climb, passing through clouds at 8000 ft., 12,000 ft. and 16,000 ft.

"At 20,000 ft., while still climbing in large circles, my goggles became frosted, making it very difficult for me to watch my instruments. When I reached 25,000 ft. I noticed the sun growing very dim, I could hardly hear my motor run, and I felt very hungry.

"The trend of my thought was that it must be getting late. That evening must be coming on, but I was still climbing so thought I might as well stick to it a little longer, for I knew I could reach my ceiling pretty soon, then I should go down, and even though it were dark, I could land all right for I had made night landings many times before; and so I went on talking to myself, and this I felt was a good sign to begin taking oxygen, and I did. I was then over 25,000 ft., and as soon as I started to inhale the oxygen the sun grew bright again, my motor began to exhaust so loud that it seemed something must be wrong with it; I was no longer hungry, and the day seemed to be a most beautiful one. I felt like singing with sheer joy as I gazed about through the small portion of my goggles which had no frost, due to a drop of oil which had splashed on them from the motor.

"When I was about 27,000 ft. I had to remove my goggles as I was unable to keep a steady climb. My hands by this time were numb and worried me considerably. The cold, raw air made my eyes water, and I was compelled to fly with my head well down inside the cockpit.

"I kept at it until my oxygen gave out, and at that point I noticed my aneroid indicated very nearly 29,000 ft. The thermometer showed 32 degrees below zero, Centigrade, and the revolutions per minute had dropped from 1600 to 1560."

# Tractor Development in Iowa

## Agricultural State Has Many Concerns—States in Grain Belt Offer Inducements for Tractor Manufacture

By P. M. Heldt\*

**M**INNEAPOLIS, Oct. 14.—It is quite evident that the center of gravity of the tractor industry will be located farther West than that of the automobile industry. Consideration of shipping conditions naturally draws an industry having a market all over the United States to the center of the country, but the fact that the early demand for automobiles was mostly from the big cities tended to draw the automobile industry eastward.

On the contrary, the early demand for farm tractors came from the large farms of the Far West. While Michigan, Ohio and Indiana are the predominating states in the automobile industry, Illinois, Iowa and Minnesota are making a strong bid for the tractor industry. In fact, much of the early work in tractor development was carried on in Iowa and Minnesota, and to-day Minneapolis possesses more individual tractor factories than any other city, though the plants of largest production are located elsewhere.

Iowa at present possesses one tractor factory having a very large output, a number of others of moderate output and some concerns still in the development stage or

just getting into production. There are also at least two important parts plants in the state.

At Clinton, on the Mississippi, is located the Climax company, which manufactures engines for farm tractors. Climax succeeded a well-known marine engine concern (Lamb Boat & Engine Co.) and the men who designed and produced the Climax have had 16 years' experience with heavy duty internal combustion engines. Climax engines are used in Square Turn, Wisconsin, Coleman and Illinois tractors among others. This engine, which burns kerosene, is rapidly gaining favor among tractor manufacturers and the company quite recently has had to build a 90 x 280 ft. factory addition, which is now in use. A new power plant containing a 250-hp. boiler, and an engine and a generator to correspond, are in course of erection. About 100 men are employed. C. B. Stebbins is president and general manager of the company, R. D. Upton, vice-president and superintendent, and J. W. Delany, Jr., secretary and treasurer.

Depue Brothers, who have built a four-wheel drive farm tractor at Clinton, are still in the development stage. The engine and its accessories and the clutch are standard parts, but the frames, axles, steering gear

\*P. M. Heldt has been making an extensive investigation of farm tractor manufacturing conditions throughout the Middle West.

*Depue four-wheel drive and steer tractor*

*Rex three-plow tractor built by the Leader Tractor Mfg. Co.,  
Des Moines, Iowa*

and final drive are of original design. A Buda Model YU engine is used, together with Stromberg carbureter, Bosch magneto, Perfex radiator, and Borg & Beck clutch.

The transmission, which is of the selective sliding type and gives three forward speeds, is bolted to the engine bell housing to form a unit power plant, and the steering gear housing is bolted to the top of the gearbox. There is no direct drive in the transmission, as at all times the drive is from the primary to the secondary shaft. The latter connects through propeller shafts to the front and rear axles, there being two Spicer joints in the forward propeller shaft and one universal of the company's own design in the rear shaft.

The feature of the tractor is the combined driving and steering axle. Both axles are alike, as the tractor is both four wheel driving and four wheel steering. The axle has a cast steel housing of the double banjo type, the differential casing being open at top and bottom. Into the top is set the gear carrier and this takes the weight of the tractor on a 7-in. Timken bearing. Axle and gear carrier can swing around a vertical axis, this motion being allowed for by a kind of fifth wheel arrangement. In the tractor built, the bearing surface of the fifth wheel is rather hard, and to eliminate the friction a row of balls will be inserted between the gear carrier flange and the stationary ring opposite it.

There is a double bevel gear reduction in each axle, the pinion on the propeller shaft meshing with a gear on a vertical axis, and a pinion at the lower end of the shaft carrying this gear meshing with the bevel gear ring on the differential. Each bevel gear set gives a reduction of 4:1, making the total reduction in the axle 16:1. A further reduction is obtained in the gearset and with an engine speed of 700 r.p.m. The tractor speeds are of  $1\frac{3}{4}$ , 3 and 6 m.p.h. The wheelbase is 99 in. and the wheels are 40 x 10 in.

As both axles have to be turned around their vertical center in steering, a very powerful steering gear is required. It comprises a 20-in. hand wheel and a single head worm meshing with a 33-tooth worm wheel. From the arm on the worm wheel shaft a heavy link extends down to an arm on a cross steering shaft under the main frame, and from this there are lever and link connections to the axle housings.

The 8-in. diameter 10-in. face belt pulley is controlled by the drive clutch and by a lever putting the driving bevel gears in and out of mesh. Completely filled, the

tractor weighs 7200 lb. It is rated as a four-plow tractor, this rating referring probably to the lowest speed. The belt speed is 3000 ft. p. m.

Depue occupies the plant of the old Clinton Brewing Co. The company was incorporated about a year ago, and its first machine was built in Kenosha, Wis.

The National Tractor Mfg. Co., Cedar Rapids, is the successor to the Denning Tractor Co. The latter concern was organized in 1910, and during its existence turned out several hundred tractors. Recently the production has been brought up to five a day, though the total produc-

tion for the current year will be only between 200 and 300.

Two models are made, a 9-16 and a 12-22. The National is a friction drive type and employs the Waukesha engine. The flywheel is developed in the form of a friction wheel, and there is a large diameter plate on either side of it which can be forced into frictional contact with it by means of a lever to give forward or reverse drive. From the friction disc shaft is spur gear drive to the differential shaft, this set of gears being located outside the frame and enclosed in a sheet metal housing. From the differential shaft the drive is through double spur gears, fully enclosed and running in oil, to driving sleeves on the rear axle to which the driving wheels are rigidly connected.

The largest manufacturer of gas tractors in the state of Iowa is the Waterloo, which was originally organized to build such machines as far back as 1893. The gas tractor was not a success at that early period, but the company got into the manufacture of stationary engines for farm use. At present it builds six different sizes of farm engines, of  $1\frac{3}{4}$ ,  $2\frac{3}{4}$ ,  $4\frac{1}{2}$ , 6, 8 and 12 hp. Only one size of gas tractor is manufactured, the Waterloo Boy, a kerosene-burning, two-cylinder, 3-plow design.

The company occupies very extensive works, two of the buildings being 1000 feet long each, and the entire plant covering 40 acres. Approximately 25 per cent of the total capacity is devoted to the manufacture of tractors, and the present output is 35 a day. While an effort was made to manufacture gas tractors in 1893, regular production of these tractors was begun about five years ago, and this branch of the business has seen very rapid development, as may be judged from the present output. About 1400 men are employed.

The engine, a two-cylinder horizontal one with opposed cranks, has a bore of  $6\frac{1}{2}$  in. and a stroke of 7 in., and a horsepower rating of 750 r.p.m. of 25 on the brake and 12 on the drawbar. One of the features of the engine is that the forward half of the crankcase can be removed, and the operator can then adjust either the connecting rod or main bearings while standing in a natural position, in which he can apply his strength to the best advantage, and also judge most accurately the character of the adjustment. All valves are located in the cylinder head, which is removable. The engine is set crosswise of the frame and an enclosed transmission is located adjacent to it. The contracting type of clutch is built

together with the flywheel and the belt pulley is located on the end of the primary shaft of the gearset, directly in line with the crankshaft. Two forward and one reverse speeds are obtained by sliding pinions. Transmission is from the primary shaft to a countershaft and thence to the differential jackshaft. At the end of this shaft are bull pinions which mesh with the internal type bull gears on the driving wheels.

The radiator is set with its face parallel with the longitudinal axis of the tractor, which makes for easy drive of the radiator fan, and also protects the radiator against trash being drawn into it. No air cleaner is fitted, but air is drawn into the cylinders through a stand pipe extending 2 ft. above the engine. The fuel tank is carried on brackets at the front end of the frame.

Steering is by a pivoted front axle and a chain extending from lugs near the ends of the axle and running over a drum operated by the steering gear. This construction will be recognized as similar to that usually employed on steam traction engines.

The Interstate, another Waterloo concern, turns out about 1500 tractors a year. The product consists of two models, one 13-30 and the other 15-30 hp. Two different sized engines are used, and though the belt horsepower of both is rated the same, it is stated that the 15-30 model has much more reserve power. Both use Buda engines, Foote transmissions and Cotta clutches. The company formerly made a small tractor known as the Plowboy. This has now been discontinued and eventually the 13-30 model will be known as the Plowboy, while the 15-30 model is referred to as the Plowman.

This concern has also been working on a new model, the Trojan, which has been demonstrated on various occasions, but which is not yet in production.

*Worm-drive tractor made by the Galloway company of Waterloo, Iowa.  
It is equipped with a  $4\frac{1}{2} \times 5\frac{1}{2}$  four-cylinder engine*

The 15-30 Plowman, with a  $4\frac{1}{2}$  by 6 in. Buda engine, weighs 4800 pounds, of which 2950 pounds is carried on the rear wheels and 1850 pounds on the front wheels. Its engine and gearset are combined into a unit power plant, from which final drive to the rear wheels is by spur pinions and internally toothed bull gears. The driving wheels are provided with cone lugs. Steering is on the Ackerman principle and the front axle is built up and has the front end of the frame pivoted to it. A Bennett air cleaner and a Bennett carburetor are fitted and kerosene is the fuel used.

Another large concern in the agricultural implement industry in Waterloo, which has been doing some work in the tractor line, is the William Galloway organization, which has been making a chain-driven tractor, and is still furnishing some of these machines; but during the past year it has developed a worm-driven job which will be its principal model in the future. The chain-driven model was first taken up 4 years ago, and possibly 800 of this type have been sold and delivered. First experiments with the worm drive are said to date 3 years back, and in January of this year the company received an order for 1080 tractors of this type from the well-known British firm of Henry Garner, Ltd. W. L. Bodman, whose name will be remembered by many whose experience in the automobile field dates back to the early years as one of the pioneers of the British steam truck industry, came to this country during the summer of 1916, having been sent by the Garner concern to look over the tractor field here and select a number of different types of light tractors which would meet the requirements of British farmers. Mr. Bodman purchased and forwarded to England samples of six different tractor types, both creeper and wheel. All these types were thoroughly tested out during the winter and spring of 1916-17. As a result of these tests orders for 1200 tractors were placed with different American makers during 1917, but owing to various causes only ten of these 1200 were delivered during the first 6 months of 1917. Mr. Bodman then returned to America, and by looking personally after deliveries succeeded in getting 250 across during the last 6 months. During this second trip to America Mr. Bodman got into communication with the Galloway company and as a result of a report which he made on its worm-driven model an order for 1080 machines was placed by Garner. Unfortunately, however, Galloway so

# Internal and Worm Reduction in Dart Tractor

By P. M. Heldt

**A** NEW final drive is the distinguishing feature of the Dart farm tractor. It combines the worm with the internal gear drive and takes account of the fact that a worm drive is most efficient at high speeds, while the internal gear drive is most efficient at low speeds.

The new machine is a three-plow tractor and is equipped with a Buda four cylinder  $4\frac{1}{4} \times 5\frac{1}{2}$  engine. Either a Zenith or Kingston carbureter is fitted, and gasoline is recommended. For regular production Dart will use the new Buda special design of tractor engine, which was not yet available when the model on which this description is based was built.

Fuel is carried in a 20-gal. tank arranged lengthwise behind the engine. A Bennett air cleaner is regular equipment. Ignition is by a Dixie magneto with hand control of the spark. The cooling water is circulated through a Modine radiator with cast top and bottom tanks and distance pieces. The fan is 20 in. in diameter and is driven by a 2-in. flat belt. Engine support is of the three-point type.

The engine, with a piston displacement of 312 cu. in., gives the tractor rating of 15 hp. on the drawbar and 30 hp. on the belt, although it is claimed that the horse-powers developed considerably exceed these figures.

A multiple-disk type of clutch is used which consists of hardened steel plates running in oil. The gearset, giving three forward speeds and reverse, is similar in design to an automobile type except that the intermediate speed is the direct drive, the high speed being geared up. The three forward speeds are  $1\frac{3}{4}$ ,  $2\frac{1}{2}$  and 5 m.p.h. Of these the intermediate speed,  $2\frac{1}{2}$  m.p.h., is the plowing speed and corresponds to direct drive.

Power for the belt shaft is obtained from the clutch-shaft through a pair of helical gears located between the clutch and gearbox. The driving member of this gearset is made of hardened steel and the driven one of aluminum

Total Reduction of  $48\frac{1}{3}:1$   
Is Obtained—Rear Wheels

4500 Lb.

*Side and front views of the Dart three-plow farm tractor*

bronze. A slight reduction of speed is obtained through this pair of gears, the pulley shaft running at five-sixths the speed of the crankshaft. The belt pulley is 12 in. in diameter by 7-in. face and is of the conventional cast-iron type. A positive clutch is incorporated in the pulley drive so that the pulley need not be kept running while the tractor is used for plowing and other field work. This clutch is of the internal and external gear type. The lever for engaging the pulley clutch has a sideward motion.

## Rear Axle Construction

Back of the gearbox a fabric-type universal joint (Thermoid) is incorporated in the propeller shaft. The rear axle construction is similar in lay-out to that of the usual internal gear truck axle, except that the bevel gear reduction at the center of the axle is replaced by a worm gear. The rear axle housing is of cast iron. The worm gear used is the standard 2-ton truck design and gives a reduction of  $9\frac{2}{3}:1$ . It operates a jackshaft on each end of which there is a spur pinion meshing with an internal gear secured to the driving wheel of the tractor. This internal gear or bull gear is completely enclosed. An additional reduction of 5:1 is obtained by this in-

ternal gearset, making the total reduction for the direct drive 48 1/3:1. The worm and worm gear are supported by a gear carrier and the whole gearset can be removed integrally from the axle housing. This set of gears is mounted on Gurney bearings, and the same make of ball bearing is used in the gearbox and in the rear wheels. The differential is a Brown-Lipe four pinion type.

The rear axle housing is an iron casting made with flanges at the ends to which are bolted two circular disks forming the covering for the internal gears. These disks are formed with lateral flanges at their circumference and the flanges are turned with a groove on the inside in which is inserted a felt packing insuring a dust-tight joint with the gear ring. The spur pinions are made of 3 1/2 per cent nickel steel, hardened, and have a face width of 2 1/4 in. Steel axle spindles are pressed into the ends of the axle casting for a distance of 8 to 9 in. and are secured in place by set screws. The front axle is of I-beam section and is also an iron casting. The front wheels are fitted with Timken bearings.

#### Frame Made of 4-In. Channel Steel

The frame is constructed of 4-in. channel steel, the channels having a weight of 6 1/4 lb. per foot. The frame extends some distance forward of the engine and has a cross-member of the same material as the side bars at the extreme front. The forward end of the frame is supported on the front axle through a semi-elliptic spring 24 in. long by 2 in. wide, which is swiveled to the axle at the middle and connects through shackles and enclosed type of spring brackets to the frame at its ends.

In addition to the main frame there is a sub-frame made up of 3-in. 4-lb. channels which are placed with the open side outward. These latter channels extend from the rear end of the tractor to about midway between the front and rear wheels, some 16 in. below the main frame channels, to which their front end is connected by brackets of 3/8-in. rolled steel.

At the bottom of the gearbox there is a lug from which extend two slanting radius rods to near the ends of the front axle and two other radius rods to a bracket secured to the front of the rear axle housing. The forward radius rods at their rear end are hinged to an eye bolt passing through the lug of the transmission housing referred to.

A flexible exhaust pipe leads to the muffler mounted crosswise of the frame close behind the engine. A muffler

*Rear view, showing arrangement and construction of the Dart tractor axle*

cut-out is provided, this being one of the few tractors so fitted. Mr. Johnson, the designer, argues that a farmer appreciates noiseless operation in his tractor as well as in his automobile and has carried out this idea throughout the design, as both the worm drive and the flexible universal joint make for noiselessness.

Most of the weight on the forward wheels is carried on roller bearings mounted at the inward end of the hubs, whereas a bronze bushing is forced into the outer end. The steering knuckles are of conventional design, and hardened bushings and washers are fitted to them. The front wheels, 28 in. in diameter by 5 1/4 in. wide, are of the built up type, having cast hubs, round spokes and rolled steel rims. A cast-iron, slightly hooded dash is bolted to the frame and is formed with a ledge on its forward side upon which the rear end of the engine hood rests, there being a corresponding ledge on the

*Side and end sections of Dart combination worm- and internal-gear double-reduction tractor axle, with worm reduction at center and internal-gear reduction at the ends*

radiator for the forward end of the hood. The hood is hinged at the center. Its sides, which hook under sheet metal angles riveted to the frame and are secured in place by means of spring type hood fasteners, can be readily removed to give access to the engine and its accessories. The fenders and dust guards are made of No. 16 gage sheet steel, reinforced and fastened together with angle steel. The forward ends of the fenders are cut off at an angle, which adds to the appearance of the tractor.

Steering is effected by means of an 18-in. hand wheel with wood rim, operating through a worm and wheel Lavigne steering gear. Spark and throttle levers are mounted on top of the steering wheel. A brake operates on the rim of the fabric type universal joint, the brake drum being  $9\frac{1}{4}$  in. in diameter by  $2\frac{1}{4}$  in. wide. This brake is operated in a very simple manner by means of a long, substantially horizontal lever to which the free end of the brake band is directly connected and the rear end of which is developed in the form of a pad on which the operator steps. In addition to this brake pedal there is a clutch pedal, the clutch operating mechanism being of the type used on automobiles, the clutch being normally held in engagement by a spring and disengaged by pressing on the pedal.

The rear wheels are 40 in. in diameter with 12 rims to which spade lugs are secured. At the rear of the tractor there is an angle steel cross bar which is bolted to the extreme ends of the frame side members and the fenders are secured to this cross bar. The cast-iron floor, with a pyramid non-slipping surface, is bolted to

both side members and the cross member of the frame.

The drawbar is of the spring type and is joined to the frame in such a way that there can be no rearing when turning corners in plowing. There are two diagonal channel steel members which are bolted to the sub-frame and which join together in the longitudinal axis of the tractor some distance ahead of the rear axle. It is at this point that the drawbar is attached.

#### Driver's Seat Mounted on C Spring

A pressed steel driver's seat is mounted on a C spring and can be swung around its supporting axis in order to enable the driver to get easily into the seat and out, and also to swing it out of the way when he wants to stand up while driving the machine. There is an arch-shaped tank support of cast iron almost directly above the rear axle. This carries the fuel tank, the magneto switch and the carburetor control.

The Dart Blue J tractor has a wheelbase of 78 in. and a tread of 52 in. measured from outside to outside of wheels. The tractor complete, but empty, weighs 4500 lb. Overall dimensions of the tractor are: Length, 125 in.; width, 56 in.; height, 65 in. The standard equipment includes a motometer, spade lugs or angle cleats and a full set of tools. Lighting and starting equipment can be furnished at an extra charge.

As in plowing the engine acts directly on the worm gear, the tooth pressures in it are no greater than in a motor truck having the same engine power and size of worm gear. All parts of the transmission are enclosed and run in oil, hence operate efficiently and noiselessly.

## Government Takes Ford Hospital

DETROIT, Oct. 14.—The Government has recently taken over the new Ford Hospital which is in process of construction, and which, with its capacity for 2000 men, will be equipped to meet all requirements, the same as a base hospital in France. It is hoped that this hospital will be open for patients Jan. 5, 1919, when it will be given over almost entirely to surgical cases. The building, 750 ft. long, is built in units, and is so designed as to give maximum light; in fact, no person can get more than  $22\frac{1}{2}$  ft. from window space. The middle unit, when completed, will be six stories high, and the two wings four. The building is being erected on a 20-acre plot on which stand the original buildings of the Ford Hospital, which were closed to the public some time ago in order that the doctors and nurses might

engage in more useful work for the Government, either in France or in cantonments in this country.

It is planned to use the new hospital as a remaking one, in which maimed will be sent to have their disabled limbs made useful. Instead of being divided into over 400 private rooms, with baths, as was the original intention, it will be divided into thirty wards, each 40 x 75 ft., and accommodating 50 men. This will permit the men to enjoy the comradeship of each other, which is desirable with such cases. When the hospital was started it was not the intention to turn it over to the Government, but now that this course has been decided upon all elaborate finishing will be neglected and no painting done. Ornamental plastering and decorating will be done when the war is over.

*Partly constructed Ford hospital, which when completed will have a capacity for 2000 men. It is expected the building will be opened for patients Jan. 5. There will be 30 wards, each 40 x 75 ft. and accommodating 50 men*

# "Which Side Are You On?"

## Employers Asking This Question Let Slip Good Opportunities

"Conditions of labor are still fluid and there is still opportunity for great advancement; we are in a most advantageous position to institute a change, to make it possible for the workman in the individual factory to take his responsibility and incentive from that factory and to secure his individual strength and his confidence from that organization, instead of the occupational labor organization, which is his only means, at present, of obtaining these things."

By Harry Tipper

**T**HE other day, in talking with a member of a state manufacturers' association, the subject turned upon labor, as it must when manufacturing problems are uppermost. This manufacturer, who is broadminded in his business attitude, said: "I note you are writing upon labor. WHICH SIDE ARE YOU ON?"

That statement explains better than half-a-book the fundamental trouble with the whole attitude upon labor questions: the assumption that an analysis cannot be made, that there must be conflict and that it is necessary to take sides. The consequences of this are seen in the constant misunderstanding on both sides as to the reasons for the adoption of policies and practical demands, and the assumption of a belligerent attitude at every turn of events.

*The object of this series of articles is to analyze the conditions and the resulting tendencies, without regard to the particular merits of any one conflict, or the particular prejudices as they exist on either side. Such conclusions as are drawn will be drawn from the analysis and will be supported by evidence that appears to be sufficient, in the writer's examination of the matter, to warrant the findings.*

No discussion of this kind can proceed very far without taking some time to consider the history and the present conditions of the labor movements in this and other countries. Unless this is done the conclusions which are arrived at will be without the qualifying statements which the traditions and precedents of such history and development demand.

The labor union is a British development, and there it has been carried much farther than in any other country. Labor movements are strong in one or two of the other European countries, but the character of the movements in these countries is different on account of the fact that they have not developed

purely as industrial movements but have been colored by socialistic aspirations from early stages in their progress.

Furthermore, the history of labor organization is the history of the British labor union, the first portion of that history having occurred before other countries had acquired any large manufacturing interests. It is for these reasons that Great Britain offers the best example of the direction and the immediate extent of the practical ideals which are behind the labor organization.

These ideals do not vary greatly, but the practice varies in degree in this country, so that the problem is not so acute and there is a greater opportunity for intelligent compromise. The direction is the same, however, and Great Britain, having traveled a good deal further on this same road, can point out to us some of the things we may expect if the labor question is left to its usual and time-honored course.

*Just as we can determine the tendencies of extreme socialistic—collectivist—government from an examination of the results of the two most far-reaching attempts at this method—the German system of complete collectivism controlled by a vigorous autocracy and the Russian Bolshevik system carried without that control—so we can from an examination of the British conditions gain some idea of the direction in which we are moving in this country.*

The conditions in Great Britain vary from those in the United States in important particulars, not only as to the progress of labor influence and organization, but as to the conditions surrounding the workers and the general attitude toward labor union endeavors.

At present the British nation, as a whole, has accepted the labor organization and has admitted the necessity for it.

In the reports of the British Commissions, which have examined into war-time industrial conditions, the necessity for strong, well-organized labor unions is frequently insisted upon. From time to time recommendations are made for the strengthening of weak labor organizations and commendations given to the stronger bodies for their value in facilitating the work. In general the hours of labor in British industrial plants are longer, the conditions of lighting, heating, and sanitation not so good as in this country. The splendid arrangements for canteen, rest, hospital, general welfare, club and other activities found in many industrial plants in this country far surpass anything at the command of the average worker over there. The opportunities for advancement are not nearly so great and the industrial system has been in action for so many years that the worker has had time to settle into a distinct class. Further, the tendency of the worker to stay in his home section and the homogeneity of the people have given this class great solidarity.

Many of the detailed reports of conditions and changes as to health measures, hours, overtime, eating, sanitation and similar matters would not apply directly to the problems as they exist with us; but even in these cases the care with which the matters have been approached and analyzed leads to some general conclusions which are of great importance, apart from the detailed figures, to every large industrial operator.

The broad position of labor in the industrial and political life of Great Britain suggests many things in the acceptance and practice which may foreshadow the things we shall be called upon to meet.

### Most Trades Strongest

In the most important trades, the railroad, iron and steel, machinery, textile, mining and maritime, the labor organizations are much stronger than they are in this country in all respects. They count among the members of the labor unions a much larger proportion of the workers, in many cases a large majority. They have had long years of unbroken development and they are well managed. They possess an influence over the industrial life of that country which is almost a definite control. With these important trades so thoroughly entrenched in unionism, the organization of the thousand and one subsidiary trades has gone ahead at a rapid pace in the last decade or so.

It is now about 20 years since these labor organizations began to secure representation in Parliament and the fact that labor members have been holding cabinet positions since the outbreak of the war is significant of the importance and influence of labor in politics. It is true that we do not have any labor party in this country, or any appearance of one, but the influence of labor organizations on politics is indicated by a number of things which have happened and this influence has not lessened any during the war—so that, even though we may never have a labor party, we must regard it as certain that labor influence in politics, once felt, will grow here as it has in Great Britain, perhaps with more rapidity.

In the important trades mentioned previously, the shop procedure as to hours, overtime, restriction of output, holidays, settlement of disputes, etc., is governed thoroughly by labor union decision and practice in Great Britain. In this country, the influence of labor has not been felt to the same extent, but again, such influence as has been exerted has concerned itself with hours, overtime, holidays, production and the same general ideas as indicated in the labor action on the other side. As this influence extends in this country, the direction of its extension is plainly marked by the conditions exhibited in the older country.

Not only is it true that in the most important trades all these questions are handled through the labor union and under labor union rules, but it was necessary for the British Government, in order to get the necessary war-time production, to agree that all changes in the practice as to hours, overtime, limitation of output, etc., should cease as soon as the war was over and the pre-war practices be considered as governing the working conditions again.

### Shop Steward's Work

One of the special features of skilled labor and recently of unskilled labor organization practice in British manufacturing is the shop steward. This is a member of the union who is selected for the purpose and whose time is paid by the other workmen of the trade in the shop. The job of this steward is to see that all the workmen live up to the union rules and to see that the foreman does likewise. All disputes between the individual workman and the foreman go through this shop steward and to him come all complaints of the management. He has no relation to the labor organization, except that he is a logical outcome of the intense interference of the labor organization with the details of shop practice, the official who must see that this mass of detailed by-law on practices is observed both by workmen and employers.

A diligent reading of the reports which have been gotten together on the industrial necessities during the war will indicate the thoroughness with which labor has interfered in the formation of every detail of manufacturing practice. The most significant part of the matter is the acceptance of the labor union's right to do these things and the necessity for the consultation of the organization upon all these matters.

*Perhaps this recognition of the right of labor to have a voice in all that concerns its conditions of work is the most valuable part of the whole matter. That question seems to have been laid away in Great Britain. The manner of its demise may involve the industrial future of the country as seriously as the question itself, but that fact can be stated as genuine progress in industrial relations.*

But there are many things which have come out of the strength and development of the labor movement in Great Britain which are so questionable in their desirability and so doubtful in their efficacy

that we would better escape them if we can. The solution to the problem of satisfied labor has not been found in their more completely unionized industries, for they are still burdened with strikes and other marks of economic warfare. More complete unionizing has handed a much larger measure of control to the worker, but does not seem to have increased the good feeling between employer and employee and does not appear to have made for a greater organization esprit de corps.

*Evidently we should be better advised to attempt other ways of solving the matter. If we leave the labor question to develop through the warfare between labor organization and manufacturers' organization, we must expect that labor organization will grow by virtue of the necessities of that warfare.*

In that case we must expect that it will gain a larger control as it has in Great Britain, that its political influence will be greater along the lines of its present development and that we shall be involved in a more serious stage of the warfare, with

less profit in it, with less chance of avoiding complete defeat and with less probability of the success of any other scheme. The longer the organized bodies continue to fight for control of these matters the harder will it be to come to peace instead of armistice.

BECAUSE OF THE FACT THAT THE MOVEMENT IN THIS COUNTRY HAS NOT YET ATTAINED THE STRENGTH WHICH IT HAS DEVELOPED IN THE OLDER COUNTRY, BECAUSE THE CONDITIONS OF LABOR ARE STILL FLUID AND THERE IS STILL GREAT OPPORTUNITY FOR ADVANCEMENT, WE ARE IN A MOST ADVANTAGEOUS POSITION TO INSTITUTE A CHANGE, TO MAKE IT POSSIBLE FOR THE WORKMAN IN THE INDIVIDUAL FACTORY TO TAKE HIS RESPONSIBILITY AND INCENTIVE FROM THAT FACTORY AND TO SECURE HIS INDIVIDUAL STRENGTH AND HIS CONFIDENCE FROM THAT ORGANIZATION, INSTEAD OF THE OCCUPATIONAL LABOR ORGANIZATION, WHICH IS HIS ONLY MEANS, AT PRESENT, OF OBTAINING THESE THINGS.

*Rear view of the latest model De Haviland 4, showing the rear cockpit for the observer*

## Features of the De Haviland 4

**Has Been Fitted with Engine of from 200 to 400 Hp.—Fitted with Two Machine Guns, One Firing Through Propeller, the Other Mounted on a Ring Surrounding the Observer's Cockpit**

**A**N important place in the American air program has been assigned to the De Haviland 4, a machine of British origin, to which frequent reference was made in a recent discussion in connection with the aircraft investigation. We have already printed a technical description of this machine, and are now in position to show a number of photographs, which will make its form more familiar to the reader.

The De Haviland 4, which was designed by Geoffrey De Haviland, chief engineer of the Aircraft Mfg. Co., is a tractor biplane, serving for reconnaissance and bombing. The machine has been fitted with a variety of engines, including a 200 hp. B. H. P., a 270-hp. Rolls Royce, a 260-hp. Fiat and a 375-hp. Eagle Rolls Royce,

and those being built in America are, of course, being fitted with the Liberty engine. The plane seats two persons, the pilot and the observer, and its armament consists of one Vickers machine gun, operated synchronously from the engine through a Constantinesco interrupter gear, and a Lewis gun. For the Vickers 600 rounds of ammunition are carried, and for the Lewis 10 drums. The total weight is 2945 lb., and the load carrying capacity for bombs amounts to 400 lb.

We have been furnished with some figures regarding the performance of the machine, but in this connection it is not stated with what engine these performances were accomplished. It is, of course, obvious that with a 375-hp. Eagle Rolls Royce the speed and climbing ability

*Three-quarter front view of the De Haviland 4. Most of these are fitted with four-blade propellers with the machine gun synchronized to fire through the blades*

will be much greater than with a 200-hp. engine. Presumably the figures apply to a plane equipped with the largest of the engines mentioned, the 375-hp. Rolls Royce. It is stated that at an altitude of 10,000 ft. the machine has an endurance of  $4\frac{1}{2}$  hours. Its ceiling is 17,000 ft. At ground level it has a speed of 117 m.p.h., and at an altitude of 10,000 ft. a speed of 113 m.p.h. An altitude of 10,000 ft. can be attained in 16 min. 18 sec.

With a span of 42 ft.  $4\frac{1}{2}$  in., an overall length of 30 ft. 2 in., and a height of 10 ft. 2 in., the De Haviland 4 is a machine of considerable size. The first specimen of this type was brought out in January, 1917, and although later models have been developed by De Haviland, the DH4 is still in active use. As will be seen from the side view, the upper wing has a considerable forward stagger, which amounts to  $6\frac{1}{2}$  in. There is no sweep-back, but both sets of wings have a dihedral angle of 174 degrees. The upper wings are attached to a center section 2 ft.  $3\frac{1}{2}$  in. wide, while the lower planes connect directly to the body or fuselage. The notable feature of construction is the slight camber of the wing ribs. The webs of the wing ribs consist of three-ply wood, and are secured to the flanges by means of brass tacks.

In the construction of the body, considerable use is made of ply wood. The forward part of the body up to a point behind the gunner's cockpit, is made without the use of diagonal bracing, and is covered by ply wood. The

formers, as well as the support for the controls and machine guns, are made of ply wood, some of which is as much as 1 in. thick. The longerons are of spruce, and the engine bearers of ash.

Most of the De Havilands are fitted with four-blade propellers, but some of them have been fitted with two-blade propellers.

### The Peterson-Culp "Super Steamer"

THE elimination of all gears, not only in the transmission system, but in the power plant as well, is the chief feature of interest in the "Super Steamer," which has been brought out by the Peterson-Culp Gearless Steam Auto Company of Price, Utah. The designs provide for the use of a double steam engine, or rather a pair of steam engines built together with a common crankcase but separate crankshafts, each of which is directly connected to one of the rear driving wheels. By this construction, it will be seen, no differential gear is necessary. Each of the two engines has two cylinders of the double acting type with a bore of  $3\frac{1}{4}$  and a stroke of 5 in. The crankshafts run on ball bearings.

The boiler is of the fire tube type, 23 in. in diameter with more than 100 sq. ft. of heating surface. Kerosene is used for fuel and the tank has a capacity of 25 gal. It is attached at the rear of the chassis.

A honeycomb type condenser makes it possible, it is said, to run 200 miles on one filling of the 30-gal. water tank.

*In this view the swivel mounting of the observer's machine gun is plainly shown*

*These charts show the various kinds of accidents sustained by employees in Cadillac plants. Through a careful analysis of such charts, together with the application of the proper remedial and protective measures, the number of accidents has been very greatly reduced*

## Accidents in Cadillac Plants Lessened

Statistics Show That Young Men Suffer Accidents More Frequently Than the Older Ones and Married Men More Frequently Than Single Ones—Classification of Accidents and Their Causes—Rendering Sandblasting Less Injurious

A VERY interesting compilation has been made by the Safety Department of the Cadillac Motor Car Co., Detroit. One of the diagrams shows the comparative number of accidents for men of different ages. Young men suffer most from accidents. This can be taken to mean that older men are more careful. The largest number of accidents recorded at any one time among men between the ages of 20 and 30 is 148, while that among men over 40 years of age was only 127. The largest number of men between 30 and 40 years of age who sustained injury through accidents during the same 5-year period was 45. All these accidents occurred during the year 1913, since which time a general decrease has been noted.

One of the other diagrams reveals the fact that accidents are more frequent among married men, although the line representing accidents to single men is not widely separated from the other. A chart giving the nationalities of the victims of accidents is rather misleading. As the biggest proportion of the employees at the plants are American it is to be expected that the

greatest number of accidents will befall them, but the conclusion should not be drawn that the proportion of accidents to the number of workers is greatest among Americans. In other words, this chart must not be considered from a percentage standpoint.

During the 5-yr. period 1913 to 1918 the greatest number of injuries reported were cases of laceration. A total of 2350 are reported on the chart. Bruises were sustained by 1530 persons. Sprains and cases of foreign bodies in the eyes total about equally—600.

About 1064 accidents occurred on machines which were in operation; 630 persons were hurt by falling objects; 273 workmen suffered injury by fellow workmen, while about 285 accidents resulted through carelessness and could have been avoided. Cases of tools breaking were the smallest in number, only thirty being recorded during the 5-year period above mentioned.

Of all injuries, those sustained to fingers were highest in number, totaling more than double those which the hand suffered during the same period. Nearly 860 accidents to

*An exhibition of broken goggles which tells a mute tale of eyes that have been saved. Bulletin boards similar to these are hung in various places throughout the plant*

*Sandblasting is done in individual enclosures, and each operator is thoroughly protected from dust. At the left is shown the inside of such a compartment, and at the right is shown the external appearance*

the hand were reported, while injuries to the fingers totaled 1820. Injuries to other parts of the body were less in number. Only 10 cases of ear accidents were reported.

Through the aid of the safety department, which has introduced safeguards throughout the various plants wherever necessary, accidents have been greatly reduced. The company offers the following figures showing the percentages by which accidents of various kinds were reduced during the period 1912 to 1916:

Nature of Injuries.	Percentage of Reduction
Grinding .....	40%
Tool slipping.....	55%
Bad practices.....	31%
Hand slipping .....	67%
Carelessness .....	78%
Machines in operation.....	48%
Fellow workmen.....	71%

One of the most unhealthful occupations was that in the sand-blast room. Breathing the sand-filled air was very injurious to the workers' lungs and the men would stay away from work several days at a time. It was necessary to have a staff of fourteen men for

this job in order to maintain a working force of twelve men. Production in this department was very uncertain, the foreman never knowing how many men he would have from one day to the next.

It was, therefore, necessary to devise some scheme which would prove more satisfactory to both the workers and the company. The men worked in a large room which was partitioned off in stalls, with one man in each stall. The partitions extended only about 7 ft. in height and offered the sand an opportunity to fill the room to such a degree that men breathed large quantities of sand, which soon affected their health.

Now individual booths are provided for the men, and all sand is confined within the walls. The men work entirely outside of the booths. After inserting his work into the booth, the worker steps before an apron and slips his arms through sleeves which permit him to handle the work on the inside. His head fits in a helmet arrangement with a glass opening permitting him to inspect his work.

## Increased Production of Artificial Abrasives

**A** MARKED increase in the output of artificial abrasives in the first half of 1918, as compared with the first half of 1917, is shown by figures compiled by Frank J. Katz, of the United States Geological Survey, Department of the Interior, and obtained in co-operation with the Mines Branch of the Canadian Department of Mines. There was little change in the output of corundum and a decrease in the output of emery in the United States.

During the first half of 1918 emery ore was produced by seven operators in the Peekskill district, in New York, and by one in southern Virginia. Corundum is produced from one mine in Macon County, N. C., and by one company operating in Renfrew County, Ontario.

The combined mine output of emery and corundum in the United States and Canada from January 1 to June 30, 1918, was 5455 short tons. During the same period the producers sold, shipped, or used in the manufacture of abrasive articles approximately 4500 short tons, and the stock on hand at the mines June 30 was about 1500 short tons.

As compared with the same period in 1917, there was a large decrease in the quantity of emery mined, and the output from January to June, 1918, inclusive, was considerably less than half of the mine output of emery for the entire year

1917. During the first half of 1918 corundum was produced at about the same rate as in 1917.

Artificial carbide abrasives, including carborundum, crysolon and carbolon, were produced during the first half of the year 1918 by two companies in the United States, operating plants at Niagara Falls, N. Y., and at Blasdel, N. Y., and by three in Canada, operating plants at Shawinigan Falls, Quebec, and at Chippewa and Thorold, Ontario.

The plant output of crude carbide abrasives was 6583 short tons. During the same period the producers sold or used in the manufacture of abrasive materials 5633 tons, and on June 30 there remained in their hands as stocks 2840 tons.

Aluminum oxide abrasives, including alundum, aloxite, exolon, lionite and natite, were manufactured in the United States by four companies, three of which operated plants at Niagara Falls, N. Y., and one at Blasdel, N. Y., and in Canada by five companies, which operated plants at Niagara Falls, Chippewa and Thorold, and two at Hamilton, Ontario.

The combined output of these plants in the first half of 1918 was 28,341 short tons. During the same period the producers sold or used in the manufacture of abrasive materials 28,161 short tons, and on June 30 there remained in their hands 26,221 short tons.

# Electric Dynamometers for Aircraft Engine Tests

Sprague 300 and 450 Hp. Dynamometers Capable of Handling Heavy Torque—Larger Type Particularly Suitable for Testing Liberty Engines

**T**ESTING the Liberty engine and other big aircraft power plants has necessitated the development of electric dynamometers of much greater capacity than those in use up to a year ago. The club test, as the fan dynamometer test is often called, has not proved to be reliable, and as a result of this there has been a strong demand for airplane dynamometers. The Sprague Electric Works are putting out two sizes for this work. The larger size has a nominal rating of 300 hp. at 1325 r.p.m. and a maximum rating of 450 hp. at 1700 r.p.m. The safe permissible maximum speed is between 2500 and 3000 r.p.m. This size is particularly adapted for testing the Liberty engine.

The smaller machine is ideal for testing the engines for advanced training planes and speed scouts. It has a nominal rating of 200 hp. at 1300 r.p.m. and a maximum rating of 300 hp. at 1650 r.p.m. The maximum free run-

ning speed is between 2500 and 3000 r.p.m. Combinations are frequently made of two of the smaller machines for testing up to 500 hp. and of two of the larger machines for testing up to 800 hp. For such tandem combinations the electrical control and torque measuring system has been worked out so that the torque is read on a single scale and the load is controlled by a single handle, just as in a single-unit machine.

These dynamometers are fitted with shaft extensions at each end, so that one engine can be set up and gotten ready for test while the other is being run. The shaft extensions are tapered to facilitate the fitting and removal of the necessary couplings.

Torque measurements are usually taken on heavily constructed beam scales, as built by the Chatillon Co., and fitted with a spring balance in series for quick indications. The Toledo Scale Co. has developed an automatic control

*Wisconsin 200-hp. airplane engine connected to 300-hp. Sprague dynamometer*

*Showing the exhaust hood used in testing the Liberty engine at the Trego plant*

indicating dynamometer scale which is very well adapted for this work, and installations of this scale are being made in a large number of plants.

#### Use Individual Rooms

Where a number of dynamometers are installed for production testing, they are mounted in individual rooms, and in each room provision is made for carrying off the exhaust gases, to eliminate any fouling of the intake air. The Ford and Lincoln companies have large numbers of these rooms for testing 100 or more Liberty engines at one time.

The engine on test is mounted on four cast-iron stands, carrying wooden engine bearers similar to those used in the plane. Rigid supports are essential to prevent vibration.

The coupling usually used is a double-flange coupling with transmitting members of Thermoid discs 15 in. or more in diameter. It is essential that the coupling be strong enough for the load and at the same time sufficiently flexible to take up slight differences in alignment. The coupling is balanced throughout and is built with a considerable flywheel effect, which is essential in testing airplane engines, even of the twelve-cylinder type.

In the earlier days of electric-dynamometer testing some engine failures were attributed to the rigidity of support and the heavy weight of the testing machine, but later investigations have demonstrated that a properly installed dynamometer equipment produces no ill effects whatever upon the engine, and an engine that is properly built for service in flight will show up well on dynamometer test.

#### Follow Cube Law

In conducting dynamometer tests it is important that the loads at different speeds follow approximately the speed-horsepower curve of the propeller that would be used with the engine. This follows the cube law. For example, if the load were 400 hp. at 1700 r.p.m., the engine should only be loaded in routine test to about 90 hp. at 1000 r.p.m.

It is claimed that results obtained on torque stands

*Engine for Class B government military truck on dynamometer testing stand in the experimental room of the Continental Motors Corp.*

clubs or propellers frequently vary as much as 10 or 20 per cent from the true horsepower output, and that calibrated clubs or rigid stands the variations have been known to be even greater. With electric dynamometers much greater accuracy is secured.

With modern types of aviation engine no difficulty is experienced in keeping the engine cool during the dynamometer test. Water is circulated through an external radiator which is kept overflowing with cold water, so that intake temperatures are maintained the same as in actual service. In the larger engines it is the practice to pump oil through an external radiator, and the intake and outlet oil temperatures can be maintained at the same as in actual service.

The blower system, with an overhead discharge fitted with a suction fan for keeping the air in the test room from reaching an excessive temperature, is an improvement to the equipment. This is shown on the test stand with the Liberty engine.

The electrical control of the machines is worked out so that the energy put into the dynamometers can be returned and they can return current to the shop system

through a fairly wide range of speed, usually from 1300 to 1700 r.p.m. For that part of the test which is conducted below 1300 r.p.m. the current is diverted into a resistor. The resistor, however, has sufficient capacity to take the entire load of the machine under conditions where it is impracticable to pump back. The control is worked out so that the adjustment of load and speed can be accomplished entirely by means of a field rheostat handle. There is one main rheostat handle and concentric weight and small handle operating an auxiliary rheostat of low resistance which gives fine adjustments of speed and load between the steps of the main rheostat. Automatic means are provided for short-circuiting the mag-

# Air Cleaners

## Analyzed and Compared

Four Types of Cleaners Are:

- |                        |                    |
|------------------------|--------------------|
| 1—Cloth or Screen Type | 2—Inertia Type     |
| 3—Liquid Type          | 4—Centrifugal Type |

Efficiency of Liquid and Gravity Types Approximately the Same—Liquid Types Because Water Aids in Carburation

By W. G. Clark, M.E.\*

**T**HE trend of engine design in the tractor and automobile field during the past few years has been more along the lines of increased efficiency of prevailing types rather than toward the development of new types of engines.

That is but a natural stage in the development of a mechanism so young as the internal combustion engine, although the demand for better efficiency has perhaps been hastened and rendered more necessary by the war. The demand for more efficiency naturally fell first on the accessory making people, especially the makers of magnetos, carbureters, bearings, etc.; and the fact that it required some time to make any appreciable progress was due to too much of the burden being shifted to the accessory firms. It is gratifying to note the rapid progress being made since the motor designers are co-operating with us and taking over their share of the work.

One of the most important single factors making for better efficiency and service in automotive work was the early recognition of the fact that dirt and carbon are the worst enemies of the internal combustion engine. Changes in design along protective lines and the application of external preventive means in the form of air cleaners have done much toward increasing the operating efficiency and life of our field engines.

The importance attributed to air cleaners by engineers and manufacturers is attested by the fact that fully 80 per cent of the tractors and several trucks furnish air cleaners as standard equipment. The specifications of the U. S. Army for trucks and tractors call for adequate air cleaning devices for the carbureters. To everyone familiar with internal combustion engines, the destructive power of dirt and other incombustible mineral matter in the cylinders is well known, so that as a means of preventing access to the cylinders of such destructive agents, the air cleaner now ranks as a most important part of field equipment.

The earliest form of air cleaner was merely a fine mesh screen of considerable area attached to the carbureter air intake. This was used several years ago but was not very efficient or satisfactory for obvious reasons.

Another of the earlier forms of cleaners was called the rain type, of which the modern air washer or water cleaner is a development. It was a modified form of the washers and

*Figs. 1, 2 and 3—Three forms of screen-type air cleaners in which flannel or eiderdown cloth is used. In the upper ones the dust laden air is drawn through the cloth. In the lower one the dust is collected on the surface without passing through*

humidifier used for cleaning and moistening air in public buildings. The cleaning was accomplished by drawing the carbureter air through a fine film or sheet of water which flowed over a screen to a reservoir and back. It was very cumbersome and impractical for field use, although if well made it was quite effective.

\*Engineer of the Wilcox-Bennett Carbureter Co. The paper published here was read at the recent meeting of the Minneapolis Section of the S. A. E.

There are several types of cleaners now in use on tractors and trucks:

No. 1—Cleaners employing cloths or screens or both to catch the dust.

No. 2—Inertia cleaners.

No. 3—That class in which water or some other liquid is used to wash the air.

No. 4—Centrifugal or gravity cleaners.

#### Screen Type Cleaners

No. 1 type, those which depend upon a cloth or screen, are practically obsolete, and rightly so, as they are troublesome, ineffective and bulky. In order to clean efficiently the cloth or screen area must be very large in order to cut down the air velocity and also to provide any considerable capacity. A cloth or screen soon clogs and restricts the flow of air to the carburetor, thus enriching the mixture. This creates carbon, causes overheating and other kindred troubles. There have been numerous forms of this type cleaner.

Fig. 1 is a type with just a cylindrical drum closed at one end and connected to the carburetor, and covered at the other end by an eiderdown cloth held in the shape of a cone by a wire at the top. The air is drawn upward through the cone of eiderdown and thence into the carburetor. In dusty field work with this cleaner the operator would have to clean the cloth very frequently or else carry a bale of clean cloths for the many changes necessary in a day's run. The type shown in Fig. 2 also employs an eiderdown or flannel cloth, but has an additional feature over Fig. 1, in that the air is forced to reverse its direction several times in passing around baffle plates. These baffle plates are intended to direct the dust-laden air into contact with the cloth.

Fig. 3 shows a cleaner employing both cloth and screen, although I rather think the screen is meant only as a means of holding the cloth in place. No provision is made for taking it apart for cleaning, which possibly is one reason we don't see many of these cleaners in use.

The second class of air cleaners I have called inertia clean-

Fig. 4—Simple form of inertia air cleaner, the open end of which is placed on the outside of the radiator. The principle of this cleaner is that the suction of air through the radiator entrains dust particles

ers, because their action depends on the inertia of the dust in the air to carry it out of the air stream when the air flow is suddenly reversed or changed before passing to the carburetor.

One form of this type of cleaner of which there are now several varieties is shown in Fig. 4. It consists of a metal casing with one side open and of rectangular shape, with a connection from the closed side to the carburetor. The open side of the casing is placed against the outside of the radiator core facing in the direction of air flow through the radiator, so that the carburetor air is drawn out of the air stream in the reverse direction. The inertia of the dust in the air being drawn through the radiator is supposed to carry it beyond the open end of the cleaner and through the radiator instead of being deflected from its path by the suction of the carburetor.

The actual efficiency of this cleaner is rather problematical, as it is very difficult to determine it since the dust cannot be measured or caught in any way. Practically the only way to test it would be to try it on an engine in the field and judge its efficiency by the condition of the cylinders.

In another form of inertia cleaner, in many respects similar to this one, the cleaner is placed behind the fan—instead of in front of the radiator so that the air is forced through the cleaner instead of being drawn through. Its efficiency, however, is dependent upon the maintenance of a certain air velocity for a given proportioning of the cleaner openings, so that a variation of fan speed interferes seriously with its effectiveness. I have no data available on these forms of inertia cleaners, but I believe that there must be a considerable volumetric loss with their use due to the fact that the carburetor air must be drawn in a reverse direction from that of the fan air stream, which possesses the kinetic energy and inertia of its velocity and direction of flow.

The third type of air cleaners comprises those cleaners or washers in which a liquid such as water or kerosene is em-

Fig. 5—Liquid air cleaner in which the dust-laden air is made to strike the surface of water before passing through the carburetor

Fig. 6—Wilcox-Bennett air cleaner, in which the air is directed to rapidly whirling water in the lower compartment through spiral passages

*Figs. 7 and 8—Two types of air cleaner in which the dust particles are thrown out by centrifugal force and collect in a container at the bottom of the device*

ployed to trap the dust. The demand for an air washer or wet type cleaner was created primarily by engine operators and owners of tractors in exceptionally dusty territories, who felt that other types of cleaners were not efficient enough for adequate engine protection. However, judging from data on most of the best air washers and dry type cleaners, I do not believe that the slight advantage of the wet type over the best dry types is sufficient to compensate for the extra troubles and difficulties encountered in the use and care of a wet type cleaner.

The best dry type cleaners will catch from 95 to 100 per cent of the dust passing into them, the efficiency varying with the fineness, weight and volume of the dust.

Under the most adverse conditions for the dry type, the best air washers will show not more than 2 or 3 per cent better efficiency. Such conditions are most frequently encountered in some of our Western States where the dust is largely composed of volcanic ash, or lava dust. This dust is very light and fine, which makes it hard to stop. It also contains considerable vegetable matter, so that of the small percentage of it which escapes the dry type cleaners, the major portion is combustible vegetable matter that will burn in the cylinders without deposit.

Many have been misled as to the efficiency of the air washer by comparing them to building air washers and humidifiers; while the action is somewhat similar, they differ in a very important respect. The ordinary building air washer deals with air at low velocities through which finely divided water particles are passed. The carburetor air washers deal with air at high velocities which must be pulled through a quantity of water.

In one case the surface of a large number of water particles comes in contact with a slowly moving volume of air affording ample time, when properly designed, to thoroughly wash all the air. On the other hand a volume of air is forced through the water at high speed. This forms air bubbles while passing through the water, which trap within themselves particles of dust. These dust particles never get in contact with the water and are carried through into the carburetor. The best carburetor air washers are those in which these air bubbles are broken up and reduced to a minimum. The presence of these air bubbles accounts for the fact that even the best air washers are not always 100 per cent efficient, especially in the extreme conditions of which I have spoken.

I know of two carburetor air washers which are not so efficient as some dry type cleaners because of this defect. Under ordinary field conditions the difference in efficiency between the wet and dry type cleaners is very slight. I think that if the truth were known the majority of tractors now

using the wet type cleaner do so on account of the moisture which they furnish to the intake air, rather than on account of any real appreciable better operation over the dry type cleaner. For some motors which do not cool any too well, especially when using kerosene, the heavily moistened and cool air from a water cleaner is almost as much a necessity as its freedom from dust. This heavy moisture content which some air washers impart causes a large water consumption, the amount varying with the temperature.

One well known air washer is said to use up 30 quarts of water in a day's work under ordinary summer temperatures. Not all of the air washers are as bad as that, but when they have to be refilled a couple of times a day, it becomes somewhat of a chore and often an inconvenience. This fact and the susceptibility to freezing in cold weather form two of the main objections of an air washer.

Figs. 5 and 6 are two forms of air washer now in use. No. 5 has the objection besides those already mentioned, that it employs a floating member with a large bearing surface exposed to the wearing action of the dust entering the cleaner. This surface is in the direct path of the dust which must effect some wear if not actual clogging of the bearing.

No. 6 is a water cleaner which the Wilcox-Bennett Carburetor Co. brought out over a year ago to satisfy certain demands for a wet type cleaner. It contains several novel features designed to eliminate as far as possible some of the objectionable properties of the wet type cleaner. It consists essentially of a centrifugal air cleaner suspended within a cylindrical casing containing a quantity of water. The water is made to revolve within the container by the whirling action of the air drawn into it from the suction of the carburetor. The water rotates because the air is drawn into it tangentially through two spiral tubes in the inner circumference of the casing.

Referring to Fig. 6, the dust-laden air enters at the side as shown and passes into the water compartment through openings in the spirals at A. The rapidly whirling air causes the whole mass of water to revolve so that it piles up against the sides in approximately the position shown by the dotted line. This completely submerges the lower ends of the spirals in a heavy spray so that all the air must pass through the water spray before escaping upward into the openings C of the inner air cleaner.

#### Effect of Centrifugal Action

The air cleaner has three spirals on its inner circumference through which the air and entrained moisture pass. The centrifugal action set up in the inner cleaner breaks up any air bubbles, completes the cleaning of the air and also throws down any drops of water that have been picked up in the air. These water drops are thrown downward and back into the water container through the open end of tube B. This reduces the humidity of the washed air and also prevents excessive water consumption. The clean air after passing out of the spirals in the inner cleaner escapes upward and out through the elbow at top to the carburetor air intake.

As long as there is any water in the container, the whirling of the water keeps the end of tube B, which is very close to the bottom of the container, sufficiently open for the thrown-down water to re-enter the reservoir. However, if the water supply is allowed to totally evaporate, enough mud and dirt will settle under the open end of B to seal it, so that even if the container runs dry, the inner air cleaner will collect the dust as a dry air cleaner. If the water container is dry and also clean, no such cleaning action is possible unless opening B is closed. Under normal summer temperatures one filling of water should last a full day's run with a tractor in the field.

The reservoir holds about 1 gal., which is a very low water consumption. The air contains so little moisture that it does not interfere with the carburetor action on gasoline as is the case with some other water cleaners. The whirling action of the water in the reservoir creates a heavy spray over the openings of the spirals so that all the air must pass through the water spray instead of bubbling through a volume of water. This practically eliminates the formation of bubbles, thereby increasing the efficiency. Furthermore, any particles

## Effects of Tractor Curtailment

THE views of the small tractor manufacturers are quite at variance with those of the large and long-established makers with regard to the War Industries Board curtailment of 25 per cent on the amount of steel and pig iron for 1919 production. Most of the large makers were pretty well stocked up with inventory on Oct. 1, 1918, which they will be permitted to use during 1919, and so the curtailment order does not affect them seriously. The small maker has not been so fortunate.

The situation of many of the smaller and newer concerns in the industry is a difficult one. Take, for instance, the case of a concern that has been preparing to place an assembled or partly assembled tractor on the market and has just reached the point where production is about to begin; it may have a large erecting plant, but, being equipped with only few machine tools, the latter is not suited for any kind of munitions work. If no material for regular production were delivered to such a concern before

Oct. 1, 1918, it seems that under the curtailment ruling it will not get any, because, as one manufacturer puts it, "75 per cent of nothing is nothing." Apparently the only thing for such a concern to do is to shut up shop and wait for better times.

In spite of such hardships in individual cases the steel curtailment may prove a partial blessing in disguise to the tractor industry, and some large tractor makers admit this. For some time past there has been a headlong rush into the tractor industry. One reason for this is that during the past year there has been a very pressing demand for farm tractors, and, besides, since the division of industries into an essential and an unessential class, the field for the company promoter has been greatly restricted.

## Production Might Have Outstripped Demand

Not only have many new companies been formed during the past year to manufacture tractors, but existing companies in many cases have enormously increased their production facilities. Under these conditions, if the development had been allowed to proceed unchecked, it is a question whether production would not soon have outstripped the demand and a serious slump set in. It is true enough that we are only beginning to introduce tractors on the farm, and that whatever number might have been turned out next year without any Government restriction would have been a small figure compared with the number that will be sold annually 10 years hence.

But it must also be remembered that the farm tractor is still in a relatively early stage of its engineering development. There are a certain number of farmers who, on account of mechanical intuition, enthusiasm for power farming, and perhaps the urgent necessity of doing their work with fewer men, will make a success of the average present-day tractor. However, it does not require a very long conversation with farmers on the subject to bring out the fact that many of them harbor a deep-rooted antagonism to the tractor. Before these more conservative ones can be converted and brought into line as tractor purchasers the tractor must be brought to a higher degree of mechanical perfection.

The restrictions imposed by the Government will give engineers and inventors opportunity to further improve their designs, and at the same time will prevent flooding the market with tractors of immature design. Commercial and engineering development must go hand in hand.

## Use American Designs

WITHOUT exception, whenever we have tried to use a foreign design of tractor, airplane engine or what-not we have run into difficulties in the shop. The Sunbeam engine, the Gnome engine, various types of tractors that can not be mentioned for military reasons, are not the only examples of this.

The difficulty starts in the engineering department, where it is necessary for American draftsmen to remake European drawings so that they can

be interpreted by American workmen accustomed to American practice.

The same trouble is encountered in the tool design department, where it is necessary to adapt American tools to foreign practice, and lastly in the shop, where the dimensions given in inches and decimals, as interpreted from the metric system, hit in his tenderest spot the workman who is used to the inch and fraction system.

Why has the Liberty engine been put into production faster than any other type since this country started to build airplane engines? Simply because it has been designed from the ground up as an American product, adapted to American machinery, and made from drawings which can be interpreted by American workmen.

After all the bitter experiences which our fac-

tories have had with work of this nature, it is folly not to read the lesson clearly.

We can make use of the knowledge incorporated in foreign designs by adapting ideas instead of dimensions. By doing this we can carry practice further in advance than is possible by a slavish copy of a foreign design which is bound to be a makeshift in the end, if it ever has the good fortune to reach the production stage.

We have had to throw up our hands on foreign designs before and we are struggling with others now on which we should have been in production if we had started at the beginning with a design adapted to our national manufacturing peculiarities.

We are fully able to stand on our own feet from a design standpoint. We have shown this in the past and it should be our policy in the future.

## Establishing An Airplane Industry

**T**HESE are days to lay deep the foundation for the American airplane industry rather than to constantly keep that group of factories now making planes on the rack for lack of contracts and the entire plane industry at 40 per cent of capacity when it should be working at 100 per cent capacity.

There is no question regarding the future of the airplane industry. It is going to be as essential as the motor truck or the farm tractor or the automobile.

To-day our policy regarding building planes and the attitude of certain governmental organizations toward our factories would not indicate that we should be laying strong and permanent foundation stones for a future great industry.

European belligerents have for some months taken definite steps in surveying the future possibilities of the airplane industry and have laid down certain basic plans for its practical working.

Already plans embrace the use of dirigibles for express service between Europe and the Americas, as well as for service to Asia and Africa. Plans also include using the large bombing types of planes for mail service.

### Mail and Express Airplanes Necessary

The value of such mail and express service lies largely in the measure of usefulness of mail and express in foreign trade business and in the necessity for such service in inter-colonial trade with such a nation as Great Britain.

Herein lies one of the strong cornerstones of the airplane industry as an essential in the peace and industrial program of a nation. Those people who look upon the bombing plane and the dirigible as only vehicles of war have failed in the comprehensive grasp of the constantly changing conditions which the hour demands.

The day is past when a round-trip mail service with Argentina covering over 6 weeks will serve to maintain necessary trade relationships. The airplane mail of one-third to one-quarter that time

must come. It is just as much a certainty as the end of the war.

The point of view of foreign trade by thousands of American manufacturers must be corrected. Those who look upon foreign trade as a business convenience by which a surplus of merchandise can be disposed of when supply exceeds the domestic demand must bury that idea with the Hohenzollern dynasty.

*Foreign trade stands as a prime essential of national greatness and national permanency.*

We must have foreign trade to secure our necessary share of the raw materials of the world that are not found on this continent.

Our gold is not sufficient surety to obtain such supplies. They can only be obtained through our foreign trade. Foreign trade at once takes on that stature which many leading European nations have attributed to it, and hand in hand with it must come air transportation.

### Foreign Trade Requires Air Transportation

Because of this, the foundation and the permanency of our airplane program becomes one of upmost importance and it seems unfortunate that at present the industry is being stifled rather than developed as it merits. The 40 per cent production stage should cease. A 100 per cent production régime should come in.

We must establish ourselves in the heavy plane industry—that is planes capable of carrying loads of 2 tons or more. That is the big future of the industry. The single-man chasse types of to-day will be of little value in commerce. The two-man planes of to-day will be of little value, but the big bombers and the bigger bombers yet to be, will be the ones that will work for national greatness.

They are the types that will accomplish most in ending the war and the ones that when peace comes will have an immediate commercial value and will admit of quick conversion from a vehicle of war into a necessary vehicle of commerce.

## Implement Dealers Losing Tractor Sales National Federation of Implement Dealers Takes Up Future of Farm Tractor Business—Tractor Is Not an "Implement" —Must Be Sold and Handled as Automobiles

CHICAGO, Oct. 11—"What will the National Federation, which represents the old line implement dealers, do to induce retail implement dealers to maintain themselves in the implement trade by dominating the tractor and power machinery business?"

This subject was the major one up for consideration at the joint meeting here to-day of the sales managers of the old line implement manufacturers and the National Federation of Implement Dealers' Association, representing 16,000 implement dealers who are supposed to sell 75 per cent of the tractors and farm machinery in the agricultural area. It is only once a year that these two organizations meet in joint session, and generally the subject of greatest importance is selected for discussion, and speakers representing both the manufacturers and the dealers are chosen.

This subject was selected this year because of the great number of automobile distributors and dealers who are selling farm tractors and who are also selling power machinery, by which is meant plows and other farm machinery, especially designed to go with tractors as opposed to corresponding machinery designed to be drawn by horses. The meeting was especially significant because many of the old implement dealers who have not taken on automobile lines have been losing that portion of their implement trade which goes with the farm tractor.

The sentiment was general that unless the implement dealer dominates in the selling of tractors and power machinery he will be wiped out. This view was expressed by P. B. Laurie, sales manager of the John Deere Plow Co., who was selected to present the viewpoint of the manufacturers of farm equipment. Mr. Laurie said:

Unless the National Federation finds a way to induce the retail implement dealers of the country to take on tractors and power farm machinery and to handle them in the right way, then the retail implement dealers who sell only horse-drawn equipment are doomed to extinction. Many retail implement dealers all over the country will not go into the tractor business, and thus the selling of tractors and power farm equipment is getting into other hands.

The dealer who sells tractors will sell also a large proportion of the power equipment as well. With tractors and power equipment in the hands of motor car dealers and others so much of the good and profitable trade will have been taken away from the

horse-drawn equipment dealer that he will be forced out of business.

It may be interesting in this connection to know the results of a recent investigation undertaken by my company—the John Deere Plow Co.—among our dealers. We found that 60 per cent of our implement dealers' agents in the States of Iowa, Illinois and Wisconsin do not handle tractors.

Furthermore, of the 40 per cent who do handle tractors only a portion ordinarily stock tractors and handle them properly. It is interesting to know, too, that of the total number of Deere dealers in these three States only 4 per cent sell the Ford car.

*As manufacturers of farm equipment we call upon the National Federation to do something to stimulate the dealers belonging to the constituent associations to get busy in the tractor business if they do not want to see it go into the hands of motor car dealers. The decision is squarely up to them.*

It is necessary and absolutely vital for the retail implement dealer, if he wants to continue in the trade, to add tractors and power equipment to his present horse-drawn lines. *Also the implement dealer must add the service which goes with the tractor business, and this, gentlemen, will take A-1 dealers. Now what are you going to do?*

The occasion was dramatic and the blunt declaration of Laurie created a sensation. It was the first public and official recognition given to the fact that motor car interests *promise to dominate in the tractor field and precipitate a new alignment in the implement business.*

Coming from the manufacturers of farm operative equipment, with the prominence of the men selected to present the subject, the incident was pregnant significant.

The viewpoint of the implement dealer was expressed by R. L. Stebbins, a Minnesota member of the dealers' organization, who contended that the tractor business belonged to the implement dealer because he was the logical man to handle it, without giving any very definite reasons for such a stand. His main thought is that the implement dealer knew how to set a plow, how to operate a silo filler, run a threshing machine, or manage a corn sheller. He contended that these were qualifications that made him the proper person to sell a tractor.

The contrary view regarding the qualifications of the implement dealer to handle the tractor was expressed by Mr. Laurie, who declared that the tractor is more like an automobile than an agricultural implement, and that it must be sold and handled as automobiles and motor trucks are. At this point one of

the implement agents interjected with "If you want us implement men to handle them," to which Mr. Laurie replied, "Make an agricultural implement out of the tractor, if you will, but if you do, then take hold of it and handle it right."

The meeting was an open recognition on the part of tractor manufacturers that the automotive dealer has demonstrated his ability to handle the tractor, and also care for the service which goes with the tractor and also with farm machinery used with it. The dealer has demonstrated his ability to give that service which keeps the tractor working as a farmer must have it.

The meeting developed the fact that several tractor makers who were also manufacturers of farm machinery have in the past years discovered that the factory cannot give the service, even through its branch house organization, which is necessary, and that it is imperative on the dealer to give this service. The experience of the year has been that the automobile dealer is not only qualified but has the capacity for such a task. It has been admitted by not a few tractor makers that it will require more than two years for the old implement dealer who has not been in the automobile trade to organize himself to give that service which is needed.

Tractor manufacturers have also discovered that the automobile dealer buys tractors in large numbers and stocks them, whereas the implement dealer does not. The automobile dealer also has been in the habit of selling for cash, whereas the implement dealer has favored long credit periods, which has been a serious handicap on his business for many years.

The National Federation of Retail Implement Dealers' Associations in turn is the supreme body in the organized implement retail world. It corresponds to a grand lodge. It is a delegate body meeting but once a year. It is composed of regularly accredited representatives from all the State associations of retail implement dealers throughout the country. The numerical aggregate of retail implement dealers represented by the State associations, and by delegates in the National Federation, is about 16,000, more than half of the recognized retail implement dealers in the United States.

It is claimed, furthermore, that these 16,000 represented dealers sell better than 75 per cent of all the agricultural implements sold in the country. This assertion is based upon the fact that the National Federation represents State associations which are located for the most part in the vast agricultural country lying between the Rocky and the Allegheny mountains. This is the territory which absorbs most of the farm equipment which is made.

These two important and representative bodies, the Sales Managers' Division and the National Federation, meet contemporaneously

## New Anderson Head Elected

**W. C. Anderson Resigns Presidency But Retains Interest—Succeeded by Townsen**

DETROIT, Oct. 16—William C. Anderson, for more than 30 years actively engaged in the carriage and electric vehicle industries in Detroit, has retired from the presidency of the Anderson Electric Car Co., which produces the Detroit electric. He will retain his interest with the company and remain in an advisory capacity as chairman of the Board of Directors. He is succeeded as president by M. S. Townsen, who has been head of the Elwell-Parker Co., Cleveland, which produces electric industrial trucks and is closely affiliated with the Anderson company.

Mr. Anderson was the organizer and head of the original Anderson Mfg. Co., which started to produce carriages in Port Huron, Mich., in 1895. Shortly thereafter the company was removed to Detroit and continued as a manufacturer of carriages and electric vehicles. In 1911 the name of the company was changed to Anderson Electric Car Co.

Coincident with the retirement of Mr. Anderson, a number of other changes have been made in the personnel of the company. G. D. Fairgrieve has been elected vice-president and general manager; W. M. Locke, treasurer; W. P. McFarlane, secretary; Wilson Critzer, assistant secretary; George M. Bacon, electrical engineer.

The Board of Directors includes these men with W. C. Anderson as chairman and J. B. Book, William H. Murphy and F. E. Price. Mr. Price, who was formerly advertising manager, hereafter will devote his entire time to the development of the sales division of the industrial truck department in Detroit and vicinities.

The company's two plants in Detroit and Cleveland have been enlarged with increased capacity for passenger cars, trucks and industrial tractors.

### Rural Express Sells Trucks

New York, Oct. 17—During the past 3½ months, 500 trucks have been sold as a result of the activities of the Highways Transport Committee in pushing Rural Express and Return Loads Bureaus propaganda, according to S. W. Fenn of the N. A. C. C., who told of the work of this organization before the Metropolitan section of the S. A. E. Geo. W. Pride, Regional Director of the committee, was

the principal speaker, and he reviewed the work and progress of the body. On Nov. 2 the Metropolitan section will make an inspection trip through the plant of the Wright-Martin Co. at New Brunswick, N. J.

### Two Dozen Companies Get Orders for 25,000 "B" Trucks

WASHINGTON, Oct. 11—Orders have been placed with twenty-four companies for 25,000 class B 3-ton Army trucks as follows:

United Motors Co.	Grand Rapids
Signal Motor Truck Co.	Detroit
Vim Motor Truck Co.	Philadelphia
Winther Motor Truck Co.	Winthrop Harbor, Ill.
Brockway Motor Truck Co.	Cortland, N. Y.
Denby Motor Truck Co.	Detroit
Lewis Hall Iron Works	Detroit
Republic Motor Truck Co.	Detroit
Bethlehem Motor Truck Co.	Allentown
Diamond-T Motor Truck Co.	Chicago
Rowe Motors Mfg. Co.	Lancaster
J. C. Wilson Co.	Detroit
Sterling Motor Truck Co.	Millwaukee
Indiana Truck Corp.	Marion
Clyde Cars Co.	Clyde
Maccar Co.	Sterling
United States Motor Truck Co.	Cincinnati
Gramm-Bernstein Motor Truck Co.	Lima
Service Motor Truck Co.	Waubash
Standard Motor Truck Co.	Detroit
Atterbury Motor Car Co.	Buffalo
Midland Motor Truck Co.	Oklahoma City
Velle Motor Truck Co.	Moline
Selden Motor Truck Co.	Rochester

### Ford's Pulley Attachment Out in November

DEARBORN, MICH., Oct. 12—Henry Ford & Son are getting ready to start production on the new pulley attachment for the Fordson tractor and deliveries will begin the second week in November. The pulley is going to be marketed without the governor attachment; the demand for the pulley being so great, the company has been induced to get the pulley on the market as early as possible and after exhaustive experiments has found that the pulley will work just as well without the governor.

The total production of tractors to date is 24,000; last week's production was 1028 and the average daily production is 170.

### Stinson Buys Stillwater Plant

MINNEAPOLIS, Oct. 15—The Stinson Tractor Co., yesterday purchased the equipment of the Stillwater Steel & Machinery Co.'s plant at Stillwater, Minn. A factory building in which to place this equipment is now being looked for. The Stillwater concern formerly manufactured the Stinson tractor on contract, but its building was requisitioned by the government.

## Seek First Bids on Militors

**Motor Vehicle Section of Quartermaster Corps Wants 20,000—Other Contracts**

WASHINGTON, Oct. 16—The Motor Vehicle Section of the Quartermaster Department has requested bids for 20,000 Militor trucks, and it is understood that orders have been placed for some 17,500 other vehicles in addition, these being Nash Quads, F-W-D, Riker, Pierce-Arrow and Garford.

The request for bids for Militors represents the placing of the first order for this new truck. This is a standardized four-wheel-drive vehicle which was first revealed at the recent meeting of the S. A. E. in Dayton. While the order is a large one, it is but natural that contracts should continue to be placed for older types of trucks to stop the gap until Militors can be delivered.

Following are the companies reported to have received contracts from the Motor Vehicle Section:

Nash	7000 Quads
Four-Wheel-Drive	4000 F-W-D
Premier	1000 F-W-D
Mitchel	1000 F-W-D
Kissel	1000 F-W-D
Locomobile	500 3-ton Riker
Pierce-Arrow	2000 1-ton
Garford	1000 2-ton

It is also stated that an order was given the Packard Motor Car Co. for Packard trucks, but the quantity has not been made public.

### Detroit Exports Establish Record

DETROIT, Oct. 14—The biggest month in Detroit's export trade was established during August, when the total exports from this district reached \$38,668,564. Of this amount, \$24,593,493 represents foodstuffs. The second largest item on the list of exported articles is iron and steel, which totaled \$4,371,905. Exports of automobiles and parts amounted to \$1,232,887.

### John D. Aitken Influenza Victim

INDIANAPOLIS, Oct. 16—John D. Aitken, who established a record as a racing driver first on National and later on Peugeot cars, died here yesterday of Spanish influenza. He was 32 years old and up to recently had been prominent as a racing driver since the days of the old Vanderbilt cup races. From 1904 till quite recently he was connected with the National company and lately had been doing special work for James Allison and Carl Fisher.

## Make Monthly Labor Surveys

### Local Community Labor Boards to Report at Request of the War Industries Board

WASHINGTON, Oct. 14—The Community Labor Boards of the Department of Labor, established in each industrial district of the country, will make monthly reports of surveys of the labor conditions in certain industries. These surveys are being undertaken at the request of the War Industries Board for the use of that board and the various branches of the Department of Labor. They include investigations of what are considered the most important and the least important industries of the country.

The United States Employment Service will co-operate with the Community Labor Boards in making these surveys. Following is the list of the manufacturing and mining industries of which the complete surveys will be made monthly:

**AGRICULTURAL IMPLEMENTS.**  
**AIRCRAFT.**—Aircraft or aircraft supplies and equipment.  
**AMMUNITION.**  
**AUTOMOTIVE.**—Including automobiles, trucks, motorcycles and accessories.  
**AWNINGS, TENTS AND SAILS.**  
**BAGS.**—Hemp, jute and cotton.  
**BARRELS.**  
**BICYCLES.**  
**BLAST FURNACES.**—Producing pig iron.  
**BOILERS.**—Stationary and locomotive.  
**BOOTS AND SHOES.**  
**BOXES.**—Wooden and paper.  
**BRASS AND COPPER.**—Rolling and drawing copper, brass, and other copper alloys in the form of sheets, rods, wire and tubes.  
**BREWERIES.**  
**CALCULATING AND ADDING MACHINES.**  
**CARRIAGES AND SLEDS.**—Children's.  
**CARRIAGES AND WAGONS.**  
**CARPETS AND RUGS.**  
**CARS.**—Rolling stock of every description.  
**CASH REGISTERS.**  
**CHINAWARE AND POTTERY.**  
**CHAIN.**—Iron and steel.  
**CHEMICALS.**—Not mines.  
**CHEMICALS.**—Mines. Sulphur, pyrites and other non-metals.  
**CIGARS AND TOBACCO.**  
**CLOCKS.**  
**CLOTHING.**—All kinds, men's and women's.  
**COAL MINES.**—Excluding anthracite.  
**COKE.**—Including by-products.  
**CONFECTIONERY.**  
**CORDAGE AND TWINE.**—Hemp and jute goods.  
**COTTON.**—Compression of cotton.  
**CRANES.**  
**DRUGS.**—Medicines and medical and surgical supplies.  
**ELECTRICAL EQUIPMENT.**—Plants engaged principally in manufacturing same.  
**ENGINES.**—Steam, gas and water.  
**FEED.**—For live stock and poultry.  
**FERROALLOYS.**  
**FIREARMS.**—Exclusive of United States Government arsenals.  
**FOODS.**—Plants engaged principally in producing food and kindred products for human consumption.  
**FOUNDRIES.**—Manufacture of gray iron and malleable iron castings.  
**GAS APPLIANCES.**  
**GLASS.**—Building, pressed and blown. Bottles and jars.  
**GLOVES AND MITTENS.**  
**GUNS.**—Exclusive of United States arsenals.  
**HARDWARE.**  
**HATS.**  
**HOUSE FURNISHING, GOODS.**  
**JEWELRY.**  
**LAWN MOWERS.**  
**LEATHER GOODS.**—Trunks, bags, etc.  
**LUMBER.**  
**MACHINE TOOLS.**  
**MATCHES.**  
**MATTRESSES.**

**METALS AND MINERALS (ferro-alloy).**—Including mines, smelters, mills and refineries.  
**MILLS.**—Saw and planing, including interior finish.  
**MINES.**—Sulphur, pyrites and other non-metals.  
**MINING TOOLS AND EQUIPMENT.**  
**NONALCOHOLIC DRINKS.**  
**OIL AND GAS.**—Producing and transporting oil or natural gas for fuel.  
**OIL AND GAS.**—Equipment for producing, refining, or transporting oil or gas.  
**PAINTS AND VARNISHES.**  
**PAPER AND PULP.**  
**PENCILS AND PENS.**  
**PIANOS.**  
**PHOTOGRAPHIC APPARATUS AND SUPPLIES.**  
**PLUMBING SUPPLIES.**  
**POWER AND LIGHTING COMPANIES.**  
**RAILWAYS.**—Not operated by United States Railroad Administration.  
**ROOFING MATERIALS.**  
**SAFES AND VAULTS.**  
**SHIPS.**—Not including those built for United States Government, its allies, or United States Shipping Board.  
**SILVERWARE.**  
**SOAP.**  
**SPORTING GOODS.**  
**STREET RAILWAYS.**  
**STEEL.**—Furnaces or mills.  
**STOVES.**—For domestic purposes.  
**TANNERS.**—Plants engaged principally in tanning leather.  
**TALKING MACHINES.**  
**TEXTILES.**—Cotton, woolen and silk.  
**TEXTILE MACHINERY.**  
**TIN PLATES.**  
**TOOLS.**—Small or hand tools for working wood or metal.  
**TYPEWRITERS.**  
**WATCHES.**  
**WIRE ROPE AND CABLES.**

Below is the form which will be used by the Community Labor Board in making out the monthly labor report.

#### Urge Abandonment of Meetings

WASHINGTON, Oct. 15—The War Industries Board has requested that because of the Spanish influenza epidemic all meetings scheduled for after Wednesday, Oct. 16, be abandoned. This does not include regular office and inter-departmental meetings, though it is urged that these be held down to as few as possible.

## Open Central School for Labor

### Chicago Manufacturers Establish Headquarters for Training Unskilled Workers

CHICAGO, Oct. 14—A central school for training unskilled labor has been established in Chicago and will be running within the next week. Local industry is watching the new training school with a great deal of interest because upon its success probably will depend the establishment of a number of others along similar lines. The skilled labor market in Chicago, which for a long time has been a difficult problem, has been made even more serious by the call for highly trained operators in other cities.

In its endeavor to find the exact reasons for the present difficulty in obtaining skilled labor for machine tool work, the Hill Pump Valve Co., manufacturing motor car accessories, conducted an investigation which showed that the labor turnover is exceptionally high, due to the competition among Chicago plants against each other for labor, by which employees were taken from one concern by offers of higher wages from other concerns, both in this city and in other cities.

This investigation showed that in many instances labor was traveling in circles, that many of the workers would jump from factory to factory at the constantly increasing offers of higher wages, and in some cases even coming back within a few years to the original factory, which had weaned them away from their last job.

The idea of a central training school

#### FORM TO BE USED IN MONTHLY LABOR REPORTS

Industry.....	Name of company.....	State.....	City.....
Classification of employees			
Principal product .....	Male		Female
	White	Colored	Total
Last pay day*.....		Male	Female
Date.....		Male	Female
8 months prior to above date.....		Male	Female
Date.....		Male	Female
Number of women at last pay day doing work done by men 8 months prior?.....			
How many of the employees are common laborers?..... Male?..... Female?.....			
What percentage of production is on war contracts?***.....			
At what percentage of total maximum capacity is plant now operating?***.....			
If production is not maximum capacity, state principal cause.....			
Remarks.....			
Date.....	Name.....	Address.....	

\*Take last pay day nearest end of last calendar month.

\*\*The percentage of output on direct Government contracts or subcontracts, or direct contracts or subcontracts with an ally of the United States.

\*\*\*This should be estimated on the normal operation of the plant, assuming all conditions are favorable for production.

Mail the above report to the BUREAU OF LABOR STATISTICS, 1712 G Street, Washington, D. C.

was placed before the different manufacturing and trade organizations of the city, and also before Chairman Miles of the Section on Industrial Training for the War Emergency Advisory Commission, Council of National Defense, and the co-operation of the Chicago Board of Education was enlisted. Through Assistant Superintendent of Schools Roberts, one of the city's school buildings in the manufacturing district has been designated as a central training school, and Chairman Miles has sent a man from his office to take charge of the school at a salary of \$6,000 a year. The Board of Education voted to spend \$10,000 for teachers, in addition to donating a school.

Several manufacturers are donating machine tools, such as automatic screw machines, drill presses, etc., duplicates of the machines that they are using in their plants, and upon which employees sent from their factories will perform the same operation that they are to perform when they have finished the course and go back to the factory.

Certain requirements are made of the factories which take advantage of the school. They must, first, furnish certain equipment, that is, machines; second, they must send a certain amount of their green help for training, and third, they must permit their foremen and other skilled workers to give some time to the school as instructors of their help.

It is the understanding that the unskilled workers who are sent from a plant must return to the plant after their course is completed. Night classes are to be established, so that those who are working in the factory in the daytime may take the school course after hours, and thus increase their efficiency and earning capacity. Unskilled help may attend the school without coming from any factory, and it is presumed that such students, if so they may be called, will be free to choose the plant that they will become allied with after the completion of the course.

#### Only Salesmen Hit by "Work or Fight" Order

ST. LOUIS, Oct. 14.—No employee of an automobile dealer with the exception of floor salesmen is subject to removal from his or her job under the work or fight order, according to a report filed with President Vesper of the N. A. D. A. by Executive Secretary E. E. Peake. This report was made after Peake and two directors had visited Washington with a view of clearing up the muddled situation as to automobile employees. His report is based upon information obtained from the Provost Marshal's office, whence comes the work or fight order.

#### Missouri Has 184,862 Cars

ST. LOUIS, Oct. 14.—The Oct. 1 announcement by the Secretary of State shows that Missouri has 184,862 cars licenses to owners. Other figures in the report are: 1648 dealers' licenses, 2340 dealers' duplicate plates, 3692 motorcycle plates, 21,087 chauffeur badges, 8500 registrations and 1485 duplicate plates.

## Women Suitable for Foundry Work

### Rest Periods and 8-Hour Day Needed—Semi-Steel Shells Asked For

MILWAUKEE, WIS., Oct. 12.—Two hundred firms connected with the American Foundrymen's Association and other metal industries contributed to the display of manufacturers' products in connection with the annual convention of that association held here this week. The attendance was the largest in the history of the association, which was largely due to the war work being done by the members of the organization. In addition to the American Foundrymen's Association the metals division of the American Institute of Mining Engineers, the American Malleable Castings Association and the iron and steel section of the American Institute of Mining Engineers also met during the convention.

#### Stress Laid on Gas Shells

Greatest stress was laid upon the manufacture of semi-steel gas and smoke shells, already undertaken in France, and about to be adopted by American manufacturers as a much less expensive but equally efficient product to be furnished the Allied armies. Members of the French technical commission were present to give information concerning the processes used in France, and a report prepared by the committee of American foundry experts acting in an advisory capacity to the Ordnance Department was presented. In this manner the entire foundry industry of America was given the first comprehensive and authoritative instruction with respect to the production of semi-steel shells, which probably will be purchased in enormous quantities by the Government within a short time.

France makes 25,000 of these shells a day. They are not so good as steel shells but are manufactured to keep the factories at a maximum point of operation, as enough steel cannot be used to keep them at maximum on steel shells. France does not want America to cut down her production of steel shells, but if possible to manufacture in addition quantities of semi-steel shells.

#### 33,000,000 Semi-Steel Shells Needed

This country and the Allies are in immediate need of 33,000,000 cast semi-steel shells, and the gray iron and malleable iron foundries of the United States and Canada must become proficient in this work immediately. All sizes of shells will be required. At first the shells will be used as gas shells.

J. A. Galligan of Chicago was of the opinion that there was enough coke to supply western manufacturers for the coming winter, but that the coal supply was doubtful. To-day 52 per cent of the railroad equipment is being used in hauling coal. Approximately 100,000,000

tons more coal will be needed this year than last.

C. E. Knoepfel of New York in an address on employment of women in foundries asserted that more women will have to be secured if the country is to put forth its maximum war effort. In many respects women are more efficient than men in foundry work and can be used for practically every purpose except heavy work. Women should be given the same wages as men. An 8-hr. day should be provided with rest periods. There should be separate entrances for the women, and as far as possible they should be segregated from the men.

#### Michigan Labor Shortage Still Critical

DETROIT, Oct. 14.—According to a report made by the United States Employment Service the state of Michigan is short 30,000 skilled and unskilled men. Camp Custer is short 2100 unskilled men and 1200 carpenters; Grand Rapids, where a large government picric acid plant is being erected, needs 1200 unskilled men and 400 carpenters; Northern peninsula requires 5000 miners, trammers and laborers and 1500 carpenters. Exclusive of this the state is reported to have a shortage of 20,000 to 25,000 unskilled men and 4000 skilled men. The office reports that the city of Detroit alone needs 1700 unskilled men, 1000 machinists and metal workers, and 1700 other kinds of skilled workers.

During the month of September the office had received calls for 21,707 men and 14,760 were sent to jobs. Of this number 6981 calls were for common labor and 4172 were sent to report for work. Records show that 75 per cent of all the men sent out on jobs are placed. It is difficult to state what becomes of the remainder. It is believed that many of the men and employers fail to send back to the Employment Office the card which is given the applicant to acknowledge the acceptance of the work.

#### Ford Employees Raise \$20,000 Worth of Foodstuffs

DETROIT, Oct. 14.—As a result of a movement started by the Ford Motor Co. employees were successful in raising more than \$20,000 worth of foodstuffs on the land which the company offered for this purpose. The land adjoins the plant buildings and has remained unutilized. The area was divided into 401 sections and each employee received 3000 sq. ft. to work.

#### Drill Chucks on Export Conservation List

WASHINGTON, Oct. 14.—Drill chucks and electrolytic cells have been added to the export conservation list by the War Trade Board, and will require individual licenses for exportation. The restrictions upon the importation of grindstones have been modified by the War Trade Board, which will now allow the importation of grindstones from Europe and Mediterranean Africa when coming as a return cargo, shipped from convenient ports, and when loading can be done without delay.

## All Pilots to Carry Oxygen

Aviators in Battle, Reconnaissance and Bombing Planes Hereafter to Have Tanks

WASHINGTON, Oct. 10—Every pilot in the American Army who goes aloft over the German lines in combat or bombing planes will carry oxygen tanks made in the U. S. A., with sufficient oxygen for from 6 to 8 hr. breathing. Pilots and observers in reconnaissance planes on photographic work will also carry them on clear days when such work is carried on at 15,000 ft. or over.

The normal atmosphere near the surface of the earth contains about 21 per cent oxygen and 79 per cent nitrogen. As the pilot ascends, the density of the atmosphere becomes less and the supply of oxygen grows relatively smaller as higher altitudes are reached. At 19,000 ft. the density of the air has diminished to the extent that each cubic foot contains only one-half the amount of oxygen as at sea level.

Pilots who are able to continue for any length of time beyond 10,000 or 12,000 ft. have a sense of "lack of air" and open their mouths in breathing to get more air. The breathing becomes quicker and deeper; the heart beats faster. They obtain the requisite amount of oxygen by increasing the amount of air breathed in a given time and by exposing a greater amount of blood to the oxygen in the air cells of their lungs.

While breathing under this pressure and really in distress, many pilots do not feel any marked inconvenience for a short period before this emergency method of getting air which nature provides gives out. He may feel perfectly fit and well but he is not as efficient as when near the ground. His reaction becomes slower; he uses longer time to judge distance; to aim his guns, to fire, and to manoeuvre his plane, although he is not conscious of this impairment. Here disaster lurks, for the pilot with swaying senses is no longer the captain of his plane. He will lose his judgment and if he attempts to stay at these altitudes will gradually pass into a condition of semi and sometimes total unconsciousness. A crash follows.

By the new process oxygen from the tanks carried by pilots flows in such a manner as to in no way impair the comfort or movements of the airman. The apparatus is simple and entirely automatic. While the airplane stands on the ground no oxygen is given off, but when it takes the air the increasing deficiency in the oxygen as the plane arises is automatically made up for by the flow of oxygen without attention from the airman.

The device which does this consists of a small tank, or tanks according to the amount of oxygen carried, the pressure apparatus, and the face mask covering the mouth and nose, and the tube con-

nected with the reservoir. This mask has combined with it the interphone whereby the pilot and observer can talk to each other with ease while in the air.

## British Air Ministry Praises Liberty Engine

WASHINGTON, Oct. 12—The British Air Ministry has officially gone on record in praise of the Liberty airplane engine and the American made De Haviland 9 and De Haviland 10 airplanes. W. C. Potter, Acting Director of Aircraft Production, received a cablegram from the British Air Ministry sent through the British Air Mission in Washington as follows:

"After 100 hours flying, one engine (Liberty) was stripped and found to be in very good condition. Tests have been made in the air in the De Haviland 9-A and De Haviland 10 machines. Engines have performed uniformly satisfactorily in these tests. Information officially expressed 4 months ago to effect that engine would prove satisfactory in service fully confirmed."

## National Aeronautic Committee Meets

WASHINGTON, Oct. 11—The National Advisory Committee for Aeronautics held its annual meeting yesterday at which reports of progress in the scientific study of flight were submitted. These reports were ordered published in the Fourth Annual Report, which will be submitted to Congress in December. The committee reviewed the present aeronautic conditions and situations, and at the same time adopted estimates for continuing further experimental and research work for the following fiscal year. Immediately following the meeting of the full committee, the Executive Committee met and elected Dr. C. D. Walcott chairman of the Executive Committee and Dr. S. W. Stratton secretary of the Executive Committee.

## Four Deaths at Aviation Fields

WASHINGTON, Oct. 12—During the week ending Oct. 5, 1918, there were four fatalities at flying fields in this country due to accidents in training. Each fatality represented 971 hours of flying or 77,680 miles in the air. Following is the summary:

Tallaferro Field, Hicks, Texas.....	3
Taylor Field, Montgomery, Ala.....	1
Total .....	4

There were no deaths reported due to flying training at any of the other 25 fields.

## Oakland Gets Bugatti Cylinder Order

PONTIAC, MICH., Oct. 15—The Oakland Motor Car Co. has been asked to supply the United States Government with cylinders for the Italian Bugatti 16-cylinder engine. Production on this contract is to start next week in the former Northway motor plant.

## Living Conditions to Be Examined

Government Commission to Look Into Situation As Means of Increasing Production

WASHINGTON, Oct. 15—The United States Government, through several of its departments, is rapidly becoming a great landlord to tenants occupying buildings erected by Government departments for the use of labor directly engaged in war work. The United States Shipping Board already has 21 housing projects under way, and the Ordnance Department has another 21 in operation. The latter project is operated on a cost plus basis by employers as agents of the Government. All told the Housing Bureau has some 60 projects of various sizes, managed by trained men.

Latterly, conditions outside the plants under which the workers of many of the war industries are living have reached the point where the production program is being seriously interfered with. In consequence the War Labor Policies Board made certain investigations and has recommended the creation of a Commission on Living Conditions of War Workers. This organization will be a branch of the Bureau of Industrial Housing and Transportation.

Its principal purpose will be to eliminate circumstances which in many cases have caused a very large rate of labor turnover with a constant retardation in production. The commission is to investigate living conditions and advise governmental agencies concerning methods conducive to maximum production. The commission will have on its staff specialists in recreation, education, public utilities, safety and sanitation.

## Motorcycle Production Restricted

WASHINGTON, Oct. 16—The manufacture of motorcycles and bicycles has been restricted during the last 4 months of 1918 to 75 per cent of production in the same period during 1917. Such ruling has been made by the Priorities Division of the War Industries Board, which states in Priority Circular No. 37 that makers must reduce their consumption of materials to three-fourths of four-twelfths of the quantity used last year in the same period. Production is not curtailed numerically by specific order. Both the Hendee Mfg. Co., Springfield, and the Harley-Davidson Co., Milwaukee, the two largest manufacturers, are engaged largely on Government work.

## Watson Heads Hispano-Suiza Section

WASHINGTON, Oct. 14—John W. Watson, president of the American Bronze Corp., Berwyn, Pa., has been appointed assistant chief of the Hispano-Suiza engine section of the Aircraft Production Board, of which B. D. Gray is chief. Mr. Watson will make his headquarters in New York.

## Imports Into South Africa

863 Cars in Last Six Months  
—Two-Thirds Less Than  
Year Ago

JOHANNESBURG, SOUTH AFRICA, Aug. 14—In the first 6 months of 1918 there were imported into South Africa 863 automobiles as compared with a corresponding 6 months of 1917, when 2529 automobiles were imported. This dropping off of imports was entirely due to lack of shipping facilities. The 863 automobiles imported the first 6 months of this year were valued at \$615,155, an average of \$712.

The importation of trucks showed a falling off also. In the first 6 months of 1918 there were only fourteen trucks imported as compared with eighteen in the first 6 months a year ago. The fourteen imported this year had a total value of \$41,765, or an average of \$3,000 each.

The importation of tires during the first 6 months of this year showed a small falling off as compared with a year ago. The tire imports this year totaled \$865,640, as compared with \$992,415 a year ago.

The value of automobile parts imported for the first 6 months of this year was \$452,685, as compared with \$524,875 in the corresponding 6 months of a year ago.

Although the importation of automobiles showed a heavy falling off in the first 6 months, the custom authorities say that a large number were imported in July, although figures have not yet been given out. One ship has just come to hand with 300 Maxwells, and it may be these belated July shipments will considerably improve the import figures covering the first 6 months of the year.

At present there are four main ports into which automobiles are imported, and of these Port Elizabeth stands first, with Durban second, Cape Town third and East London fourth. The figures showing the number of cars imported at these ports are as follows:

Port	Cars	Trucks
Port Elizabeth .....	359	3
Durban .....	257	0
Cape Town .....	122	2
E. London .....	112	9
Other Ports .....	13	0

Car prices increase with every few shipments. It was mentioned in error in a previous article published in AUTOMOTIVE INDUSTRIES that the Ford price was \$1,575. It is only \$1,250 for the regular model.

A few years ago Cape Town was the port for inland automobile traffic. Now most of the cars pass through Durban and Port Elizabeth. Durban is 500 miles from Johannesburg, Cape Town 1000 and Port Elizabeth 750. But it is found that upward of 10 days are saved by off-loading at Port Elizabeth.

This is chiefly because Durban is fast becoming the general port for the Union,

and the railroads and docks are not up to the traffic. So wise dealers get their cars off at Port Elizabeth. Also at Port Elizabeth ships are not off-loaded by the South African railways and harbors—the Government Service—but by a company contract, and they seem to get through the off-loading better.

Durban is now the port for the interior and a fast rising city.

## Liberty Engine Production Totals 10,151 to Oct. 10

DETROIT, Oct. 15—The total production of Liberty engines on Oct. 10, including all makers, was 10,151, these being distributed among the various makers as follows:

Lincoln .....	2,824
Packard .....	3,965
Ford .....	2,010
General Motors .....	1,144
Nordyke & Marmon .....	208
Total .....	10,151

The number of engines shipped by these various companies is slightly lower than the total production figures. This is due to the fact that a certain proportion of engines may be practically 99 per cent assembled but held up for some minor detail. Such details may be completed on a large number of engines in one day, thus pushing daily shipments considerably higher. Following are the numbers of engines shipped from the various plants:

Packard .....	3,696
Lincoln .....	2,601
Ford .....	1,766
General Motors .....	961
Nordyke & Marmon .....	139

## Russell Profits \$628,581

TORONTO, ONT., Oct. 15—During the fiscal year ending July 31 the Russell Motor Car Co. made net profits of \$628,581.55, and though this is approximately \$15,000 less than for the previous year, it includes allowances for war profits tax and other contingencies. The balance carried forward shows a marked increase from a year ago, the amount being \$536,162.22 as compared with \$47,580.67. Following is the balance sheet:

Assets	
Cash on hand and in bank .....	\$175,461.55
Accounts and bills receivable .....	313,830.19
Investments in other companies .....	3,793,387.47
Dominion of Canada War Loan .....	321,947.25
Stock on hand, manufactured and in process, raw materials and supplies .....	137,084.91
Insurance, fuel, etc. ....	7,881.55
Real estate and buildings .....	54,583.25
Machinery, tools, patterns, furniture, etc. ....	192,666.61
Less depreciation .....	25,699.24
Total .....	\$4,871,143.54
Liabilities	
Bankers' advances .....	\$325,000.00
Accounts and bills payable (including war tax) .....	1,014,600.93
Dividends declared and unpaid .....	77,000.00
Contingent account .....	216,075.50
Plant investment and insurance reserve .....	802,304.89
Capital stock (preferred, \$1,200,000; common, \$800,000) .....	2,000,000.00
Profit and Loss account .....	536,162.22
Total .....	\$4,871,143.54

## Clear Convoy Routes of Snow

Highways Transport Committee Prepares Plan to Keep Roads Open

WASHINGTON, Oct. 12—The Highways Transport Committee, Council of National Defense, of which Roy D. Chapin is chairman, is preparing plans for the removal of snow from motor convoy routes extending from the north and middle western states to the seaboard during the coming winter.

The committee, which was effective in this work last winter, will use its complete organization, comprising the regional directors and the State Highways Transport Committees, in co-operation with the Motor Transport Corps under General C. B. Drake, in this work.

The State Highway officials of Pennsylvania, New York, Ohio, Illinois, Indiana, Michigan, New Jersey, Massachusetts, Connecticut, Delaware and Maryland, which co-operated with the committee and the War Department most effectively last winter, will be called upon again to arrange plans for the snow removal program which is now contemplated.

The New York Legislature has provided Highways Commissioner Edward Duffy of that state with a fund of \$50,000 to be used in keeping the roads traveled by Government trucks clear of snow. Arrangements have been made with Prof. Charles F. Marvin, Chief of the Weather Bureau, by the committee, to have forecasts made from different observation points in the territory to be covered by motor truck routes at least three days in advance of the starting of the trains. In this way it is expected that the organization will be able to anticipate coming snowfalls and guard against them.

Lieut.-Col. W. D. Uhler of the Motor Transport Corps, in co-operation with the committee, is outlining his plan of motor transportation over three main truck routes, one starting from Chicago, one from Detroit and one from Buffalo, and all converging at Baltimore.

Colonel Uhler is also making plans through the use of the army for removal of snow in co-operation with the committee and as soon as his plans are completed they will be announced. General Drake, in a letter to the Highways Transport Committee asking for its co-operation in the removal of snow from truck routes, suggested that the route from Chicago to Baltimore be as direct as possible, the one from Alma, Michigan, via Detroit to Baltimore and that from Buffalo via Albany to Baltimore.

The moving of motor trucks under their own power from factory to seaboard has grown until now there are as many as 500 traveling over the highways in a single day in separate convoys, and by the time the winter snows fall these numbers will have increased considerably.

# Trade Reconstruction Policies of European Belligerents

## U. S. A. Government Report Gives Comprehensive Analysis

WASHINGTON, Oct. 14—The Government has issued its first report on reconstruction work following the war which has been issued through the Bureau of Foreign and Industrial Commerce which contains an analysis of the main tendencies toward reconstruction in the different belligerent countries of Europe. The reconstruction programs in England, France, Italy, Germany and Austria are outlined and an analysis of each given.

This monograph together with the fact that there are certain Washington representatives in Europe studying reconstruction problems suggests that at last Washington has gotten under way its reconstruction program.

In all of these European reconstruction programs the control of raw materials assumes a major place, and already Great Britain and some of the other countries have entered into agreements with their colonies regarding raw materials.

There is a general sentiment as deduced from an analysis of European reconstruction work that the Government control of an essential product may be converted into a valuable political asset and that political contingencies may make it necessary to keep such a product out of the influence of free economic laws.

Among the high spots brought out in the analysis is the suggestion that there seems to be a general fear that the middle man may be eliminated from the economic structures of some countries after the war.

Germany seems to favor a monopoly on the importation of raw materials as a means of mobilizing the purchasing capacity of the country to counteract economic discrimination.

France holds favorably toward monopolies, a policy which she has stood by in the past.

### Co-operation in Britain

In Great Britain and Germany two parallel movements in the work for after-war conditions are seen. In each country the government is creating new instruments or overhauling the old in order to be ready to meet the new conditions created by the war, and private organizations in commerce, industry and finance are getting closer together and co-ordinating their efforts so as to present a solid front to the anticipated onslaught of their old rivals.

While the different countries are preparing for post-war conditions Great Britain, which has been a leader in this

### Some Conclusions

- A—Government Control of Industries Will Increase.*
- B—Government Control of Raw Materials to Follow.*
- C—Middleman May Be Eliminated in Some Countries.*
- D—France Is Favorable to Certain Monopolies.*
- E—Germany Plans Monopolies on Raw Materials.*
- F—Business Concerns Uniting for Trade After War.*
- G—European Plan to Reorganize Consular Service.*
- H—Great Britain Reorganizing System of Technical Education.*
- I—Three-Year Control of Exports After Peace by England.*
- J—Working Clause in Patents and Trade Marks Urged.*
- K—Banking Amalgamation Started in Germany.*

movement, is not at present attempting to lay down any complete or binding policies regarding the future, but looks upon such as a waste of effort. Her work at present consists in assembling of facts and taking basic steps to improve educational research and promote organizations so as to contribute to clear thinking on the questions involved.

Such expedients as a Webb-Pomerene Bill, authorizing the combination of exporters for foreign trade purposes, the Federal Reserve Board and national banking system with their wide leeway in foreign trade banking matters, the Federal Board for Vocational Education developing the fundamentals of reconstruction by consideration of general vocational training, and the collections of statistical data and research investigations by the Department of Labor, Department of Agriculture, Bureau of Mines and the Geological Survey of the Department of Interior, the Bureau of Standards and the Bureau of Foreign and Domestic Commerce of the Department of Commerce, the United States Shipping Board, War Trade Board, War Industries Board, the State Department and the United States Tariff Commission, are all a considerable amount of quiet and effective work that will be found decidedly constructive in the formulation of the policies of the United States for after-the-war business. With the co-ordination of the efforts of all these departments under one Government office much will be done toward safeguarding the economic future of this country.

These views expressed in a bulletin on economic reconstruction prepared by the

Bureau of Foreign and Domestic Commerce of the Department of Commerce embody the opinions of official Washington on a subject which is receiving not only consideration but considerable action among both our Allies and the Central Powers. In fact, steps are now under way in this country for an enlarged program of economic reconstruction. Walter S. Gifford, Director of the Council of National Defense, is at present investigating and consulting on the subject with British and French authorities in London and Paris. Plans are being considered for the conversion of the Council of National Defense into a vehicle suitable for handling these matters, for making it into a body possibly similar to the Reconstruction Committee of the British Ministry of Munitions.

### Many Plans Adopted

Although the tendency to consider economic factors for after the war as retaliatory weapons is now far less pronounced, states the bulletin of the Department of Commerce, than it was during the period of the Paris Economic Conference, every belligerent country of commercial or industrial importance is considering the economic problems that will arise after the conclusion of peace. Many ambitious schemes have been adopted, but these will of course be modified in accordance with the duration and outcome of the war. But there are certain well defined tendencies and some parts of the program of the more important countries which have received official sanction or been adopted by legislation. These should be considered by the United States because although

many of them are unsuitable or unnecessary for this country they may prejudice its interest in foreign fields.

#### Government Control to Increase

There seems to be a unanimous opinion that Government control of and participation in trade and industry in all of the belligerent countries will increase. Admissions of the inevitability of this have been made by even the strongest opponents of the governmental control policy. The chief reason and probably the factor which no opposition can combat lies in the fact that the ordinary sources of revenue of each nation will be insufficient to bear the enormous fiscal burdens and **THE GOVERNMENTS WILL HAVE TO GO INTO BUSINESS TO PAY FOR THE COST OF THE WAR.**

In addition to this important factor are two others developed as a result of the war and which will undoubtedly influence government control seriously. These are:

##### Economic self-sufficiency.

National control of raw materials and essential products.

Economic self-sufficiency has developed with the war which has proven it a political necessity. Governments must be self-sustaining. National control of raw materials and essential products is another factor developed by the war and is closely related to the problem of self-sustenance. Both Great Britain and Germany are giving much attention to these ideas—England because of the great extent of the natural wealth of its empire and Germany because of the lack of such wealth in its boundaries. The war has developed the fact that control of essential products by a country may convert it into a valuable government asset, and that it must be kept free from the influence of general economic laws of supply and demand and price fluctuation. If such control is found necessary after the war it is almost certain that it will be a government control; and if the control produces increased profit, opinions, according to the Department of Commerce, are that the Government should receive at least a good share of such profits to be applied to the obligations created by the war and for the promotion of the many plans for social betterment.

The entry of the United States into the war and the Russian revolution are considered as disturbing elements in the original plans for economic pact of retaliation on the part of the Allies and the economic alliance of the Central Powers. An economic union between Germany and Austria-Hungary, however, is regarded as a certainty by economists in both countries, although considerable opposition has developed on the part of commercial interests in the Baltic ports and Hamburg as well as by the Agrarians in Bavaria.

#### Governments Enter Commerce

Both Germany and Great Britain have established new departments of commerce, the Ministry of Reconstruction in

Great Britain and a similar department in Germany, which forecast ambitious plans for after-war world trade. Plans for the reorganization of the consular service and technical education in Great Britain, waterways extension in France, Germany and Austria-Hungary, reorganization of credit institutions in Great Britain and France and the restoration of the merchant marine are movements that forecast these schemes.

German economic life has probably changed more than that of any other country. This is due to the great government control exercised during the war, the intensive paternalism developed by the war and the economic pressure caused by the blockade of that country's boundaries. As a result the German problem resolves itself into two phases:

a—Government control during the emergency period, primarily for economic reasons.

b—Permanent government control, primarily for fiscal reasons.

Germany cannot transform itself suddenly from the present extensive scheme of government control and paternalism into a normal competitive regime without creating serious economic and social complications, particularly in the problems of exchange, shipping and raw materials supplies. Even the commercial interests which have complained bitterly against the German war policy that has eliminated the middlemen admit the need of retaining the present economic organizations in charge of raw materials and foodstuffs for some time after the conclusion of peace, although they urge the abolition of these organizations as soon as possible to allow the restoration of those economic forces which created Germany's economic progress in the past. At present the German economic scheme includes, importantly:

- 1—Imperial control of cargo space.
- 2—Imperial control of import rationing and prohibition.
- 3—Imperial control of foreign credits.
- 4—Imperial supervision of exports of raw materials and manufactures.
- 5—Imperial control of the distribution of imports to equalize industrial reconstruction.

In a recent statement before the Reichstag the Secretary of State for Economics stated that so long as the supply of raw materials after the war will be inadequate, the government will have to retain control for the protection of the weaker interests. He stated also that he was taking the threat of an economic boycott on the part of the Allies seriously and making preparations to meet such an emergency. Later in the spring of 1918 the German Government stated that while it does not intend to regulate all commerce and industry it will interfere in the supplies of rubber, oils, leather and hides and such commodities as may be inadequate to meet the demands. In other commodities where there will be a considerable surplus the state will interfere to prevent excessive imports. Present plans include the creation of a number of economic offices to co-operate with the present war

companies which will be reorganized on a peace basis. Various trades and industries will be represented by individuals to be nominated by the industrial, commercial and labor organizations subject to the approval of the Secretary of State for Economics. For some time after the war it is expected that German tonnage will be reserved principally for essential imports which will be controlled by an expert commissioner from the Ministry of Economics. Plans also call for government control of freight rates.

#### Britain to Control Exports

British activities indicating government control for after the war include the introduction of an Imports and Exports Bill providing temporary control for 3 years after the conclusion of peace and a recently adopted Non-ferrous Metal Industry Act giving the Board of Trade control of the business in non-ferrous metals and ores. This last measure is intended primarily to eliminate enemy interests, but is also considered a movement toward government control. At the last meeting of the British Associated Chamber of Commerce it was stated by Sir Albert Stanley that at the close of the war practically all trade and industry of the country will be controlled directly or indirectly, and that it will be the function of the government to immediately abandon these controls as soon as it will be compatible with the national interests. He does not believe, however, that it will be possible for the government to give up its interests in the railways and canals and allow them to revert to their pre-war state.

Continuation for at least 12 months of the existing prohibitions against enemy imports and for government control of exports of essential raw materials is advocated by the Committee on Commercial and Industrial Policy After the War. The London Chamber of Commerce has on several occasions warned against "perpetuation of those methods of expediency justified by the war for after the war." There is a fear that the middleman will be eliminated from the economic structure of the country, a possibility that has considerable opposition.

Organized labor in Great Britain favors government control, a natural attitude in view of the results to labor. At a recent meeting the Labor Party demanded immediate nationalization of railways, mines, production of electrical power and a continuation of the existing government control of commerce and industry for after the war.

#### Germany to Have Monopolies

The establishment of monopolies as the best practical method of exercising government control is advocated by economists in each of the different countries. Some economists prefer monopolies as against capital levies. There is a German tendency toward monopoly of the import of raw materials as a method of mobilizing the purchasing power of the country to counteract economic discrimination and also as a means of increasing the revenue by depressing the

purchase price abroad and raising the selling price at home. It is also claimed that this form of monopoly would only affect import trade and leave the internal trade undisturbed.

Monopolies in France are established government institutions. This country has long had monopolies of manufacture and sale of some commodities. A monopoly of petroleum is now being suggested embodying the taking over of the existing highly concentrated import trade and refining industry. The British monopoly of petroleum is also being considered in connection with a possible exploitation of the Persian oil fields.

#### Britain to Control Resources

To secure economic self-sufficiency and national control of essential products the Dominions Royal Commission of Great Britain is investigating the development of the resources of the empire and the prevention of foreign control of such resources. Some sort of department will be established to secure the information of the requirements of the empire in essential products and their actual and potential outputs. An example of the plans of the British Government for the control of national resources is displayed by the recent agreement with the Australian Government by which the output of zinc concentrates will be controlled for the period of the war and 10 years following. The British Government takes the stock of zinc concentrates on hand Dec. 31, 1917, leaving a specified percentage reserve and 250,000 tons yearly for the duration of the war and one year following, and 300,000 tons annually for the succeeding 9 years. It also retains an option on the balance of production, subject to reservations such as the requirements of the Australian zinc refining works and the fulfillment of existing contracts. There is also a tendency in Great Britain for at least a temporary protective policy over certain industries, calculated to shut off imports of specific German products such as magnetos.

France will be busy for years after the war with the restoration of the invaded districts, and realizes that it will not be able to engage in comprehensive plans of economic reconstruction. Consideration is being given to the development of water power resources, coal and colonial activities, and it is likely that agriculture will be stimulated.

#### Great Britain's Policies

Briefly summarized the British Government in order to meet the problems following the conclusion of peace has developed the reorganization of the War Trade Board corresponding to the Department of Commerce of the United States; the British Ministry of Reconstruction to continue for 2 years after the war, designed to co-ordinate all the departments bearing on reconstruction and which is divided into branches dealing with commerce, production, material supplies, finance, shipping, labor, rural development, health, education, housing and internal transportation; patent and trade-mark legislation; technical educa-

## Rubber Imports Still Decline

### Total for 9 Months Below That of Last Year—All Free Rubber Now Received

NEW YORK, Oct. 11—Imports of crude rubber continue to decline. The total to date from the first of the year is less than for the same period in 1917. During the first 9 months of 1917 the total importations touched 136,325 tons, whereas during the first nine months of 1918 the total was 131,132 tons, which is a loss of 5193 tons.

Imports during September were less than half those for August, 5151 tons coming in during September as compared with 10,421 tons in August; this is a drop of 5270 tons. Imports during September, 1918, were considerably less than one-third the tonnage that came in during September, 1917, a comparison of these two months showing a loss of 8513 tons.

Practically the entire amount of September importations is allocated rubber, substantially all of the free rubber shipped prior to May 8, 1918, having reached this country. According to the rulings of the War Industries Board, importations of rubber have been restricted to 25,000 tons during the last quarter of the year, which means that the monthly allowance is approximately 8300 tons. September, of course, dropped considerably below this figure, so that the difference between the actual imports and the allowance will be permitted to come in during October. It is understood that there is quite a quantity of rubber on the seas and that imports will practically equal the quantity permitted to come in.

Following are the statistics as compiled by the Rubber Association of America:

Month	1917, Tons	1918, Tons
January .....	12,788	16,084
February .....	10,162	13,108
March .....	18,624	17,161
April .....	13,000	12,703
May .....	18,411	16,288
June .....	15,096	24,124
July .....	17,290	16,092
August .....	17,290	10,421
September .....	13,664	5,151
Totals .....	136,325	131,132

tion and the Registration of Business Names Act. The Ministry of Reconstruction is assisted by an advisory council representative of all the leading interests concerned in reconstruction. The section of the advisory council working with the branch dealing with finance, shipping and common services is at this time engaged on the problem of the disposal of government stores after the war. This problem is regarded as so important that a special body will be created to take charge of the work and act as a selling organization for the government departments having surplus stocks to dispose of. Army demobilization is being considered and plans are now being formulated.

The Board of Trade has introduced two measures providing for strict application of the working clause in patent and trade-mark legislation, for greater facilities for licensing and for revocation of patents when patent rights are abused as, for example, failure to work the patent, to grant licenses on reasonable terms or unfair conditions imposed on the sale or use of the patented article. The regulations are intended to prevent the abuse of words as trade-marks and to provide facilities for the registration of marks which could not be registered under past legislation. The Registration of Business Names Act compels the registration of real names, surnames, nationality, nationality of origin, usual residence and other business occupations of the directories of all companies registered in Great Britain or with an established place of business in the country.

#### Britain's Technical Education

Technical education is to be promoted and is receiving the consideration of a number of committees. Five million dollars has been obtained from Parliament which is to be expended for this work. Private efforts in Great Britain include banking amalgamation, industrial amalgamations, such as the organization of the United Steel Companies, comprising six concerns and capitalized at \$50,000,000; the British Trade Corp., which will supply extraordinary credit to concerns that are members and to colonial concerns allied with it; the Federation of British Industries, an association of British manufacturers, which assists the government in framing industrial legislation, settling labor difficulties and the promotion of British trade interests; the British Empire Producers Organization, designed to create economic self-sufficiency for the British Empire; the British-Italian Corp. for the promotion of closer trade relations between the two countries.

In France the Association Nationale d'Expansion Economique has undertaken a comprehensive economic survey of the country, and the Comité Republicain du Commerce, de l'Industrie et de l'Agriculture has investigated organizations and published the results, expressing their views in regard to the changes in economic structure necessitated by the war together with preparations for the future.

The Imperial Ministry of Economics created in Germany is divided into two main sections, one dealing with war economics, tariffs, monopolies, syndicates, etc., and the other with such social questions as unemployment, insurance, savings, housing, etc. Bank amalgamation has also taken place in Germany. An export trade organization somewhat like the British Trade Corp. has been capitalized at 25,000,000 marks and will undertake the construction and operation of railroads, harbors, electric plants, factories, etc. There is also a movement for the establishment of a special bank for export trade to insure that small German concerns will receive acceptance credits in the countries now at war with Germany.

## Tax on Car Owners Cut 50%

### Senate Committee Halves Original Figure—Consider "Gas" Tax Effect

WASHINGTON, Oct. 12—The Senate Finance Committee yesterday reduced the tax on users of automobiles 50 per cent, lowered the tax on sight-seeing automobiles and taxicabs and gave consideration to the possibility of seriously affecting gasoline production through the proposed gasoline tax. New automobile taxes to be put on the users of cars as agreed to by the committee follow:

23 h.p. or less.....	\$5
Between 23 and 30 h.p.....	10
Between 30 and 40 h.p.....	15
Over 40 h.p.....	25

Electric automobiles will pay \$2 per horsepower instead of \$5, as was fixed by the House, and 25 cents for each 100 lb. of weight instead of 50 cents.

The tax on sight-seeing automobiles was changed from 10 per cent of the gross receipts to a flat tax of \$20 per year per vehicle.

The tax on taxicabs and other automobiles operated for hire, carrying not more than seven passengers, was changed from 5 per cent of the gross receipts to a flat tax of \$10 per car per year.

The committee also listened to Mark L. Requa, Director of the Oil Division of the Fuel Administration, who told of the shortage of gasoline and the needs for it for war purposes, and urged that special consideration be given to the oil producers in the revenue legislation. At present the revenue bill as passed by the House provides for a tax of 2 cents per gallon of gasoline.

### Chevrolet-General Motors Merger Ratified

NEW YORK, Oct. 14—The merger of the General Motors Corp. and the Chevrolet Motor Co. has been finally ratified,

the stockholders voting at a meeting last Friday to adopt the basis of exchange originally laid down. Under this arrangement, holders of Chevrolet stock will receive one and one-seventh shares of General Motors common and 44 cents in cash for each share of Chevrolet. The General Motors Corp. has declared a dividend of \$3 per share payable Nov. 1 on common stock of record Oct. 18. Hence, stockholders who prior to that date forward their certificates to the Guaranty Trust Co., New York, properly endorsed, will receive this dividend. Stock delivered after this date will not carry the dividend but holders will receive an equivalent amount from the Guaranty Trust Co. Following is the balance sheet of the Chevrolet Motor Co. as of Oct. 11, 1918:

Assets	
Cash .....	\$278,042
732,680 Shares G. M. Common.....	73,268,000
Total .....	\$73,546,042
Liabilities	
Capital stock outstanding, 641,095 shares .....	\$64,109,500
Surplus and undivided profits.....	9,436,542
Total .....	\$73,546,042

### Electric Storage Battery Has Record 6 Months

PHILADELPHIA, Oct. 15—During the first 6 months of 1918 the Electric Storage Battery Co. realized profits only slightly less than the amount realized during the whole of 1917. In 1917 the profits were \$2,220,613, as against \$2,000,000 for the first 6 months of 1918. The earnings are at the rate of over 26 per cent per annum on a capitalization of \$16,130,000. The company is largely engaged on government contracts but is doing work with which it is thoroughly familiar and which has not required extensive plant additions. Following are comparative earnings since Jan. 1, 1910:

Year	Net Earnings	Net Income
1917.....	\$2,220,613	\$2,477,882
1916.....	1,318,796	1,582,058
1915.....	1,188,618	1,360,748
1914.....	848,628	1,103,238
1913.....	1,035,918	1,208,765
1912.....	1,023,836	1,125,280
1911.....	1,026,747	3,263,608
1910.....	871,573	1,120,012

## General Motors Nets \$26,078,120

### Profits During First Six Months of 1918 at Rate of 10.28% on Common Stock

NEW YORK, Oct. 15—General Motors Corp. for the first 6 months of 1918 showed earnings on common stock at the rate of 10.28 per cent in excess of the 12 per cent dividend now being paid. During that period it realized net profits, after deducting taxes, insurance and depreciation, of \$26,078,120. The surplus for the 6 months after paying dividends at the rate of 6 per cent on the preferred stock is equal to 11.14 per cent on the \$105,141,700 of outstanding common stock; this is at the rate of 22.28 per cent per year.

Following is the balance sheet as of June 30 compared with the balance sheet as of Dec. 31, 1917:

Assets—	June 30, '18	Dec. 31, '17
Permanent investment	\$68,708,687	\$38,931,930
Miscellaneous invests.	5,922,688	2,030,274
Cash .....	31,186,737	18,865,640
Liberty bonds.....	9,098,123	1,255,009
Notes and accts. receivable .....	23,975,413	13,595,539
Inventories .....	56,219,729	46,559,394
Deferred expenses....	1,281,360	854,435
Good will.....	.....	*11,697,503
Total assets.....	\$196,342,737	\$133,789,724
Liabilities—	June 30, '18	Dec. 31, '17
Preferred stock.....	\$19,676,800	\$19,676,800
Common stock.....	105,141,700	76,873,300
Outstanding stock sub. cos. not owned by G. M. Corp.....	540,500	540,500
Surplus sub. cos.....	1,138,558	859,083
Accounts payable.....	16,032,126	10,665,718
Notes payable .....	1,100,000	.....
Taxes, pay rolls, etc..	7,287,600	4,858,327
Reserve for two months proportion preferred dividend..	190,768	196,768
Reserve for Federal taxes and extraordinary expenditures..	15,865,735	6,939,019

Surplus .....	26,705,753	11,508,392
Total liabilities.....	\$196,342,737	\$133,789,724

### Curtail Electric Heaters

WASHINGTON, Oct. 14—The War Industries Board has ruled that the manufacture of certain electrical heating appliances, including carburetor heaters, hand wheel heaters, intake heaters, manifold heaters, primer heaters, cigar lighters and foot warmers, must be discontinued after Dec. 27, 1918. Prior to that date, manufacturers of such devices will be permitted to match up their stocks and to continue the manufacture of such products as are partly manufactured and to use up stocks of materials on hand. After Dec. 27, however, manufacture of the above mentioned devices must cease absolutely.

This board has been the means of stimulating production at the forge shop of the Timken-Detroit Axle Co. During August (when the plan was inaugurated) the men aggregated an output 26 per cent in excess of the average production for the previous 6 months. The men know by referring to the board the quota they must meet each day; if they fail to meet it, the figure of the Hun is put ahead of that of the Yank and ~~stay~~ there until the latter regains his ground. The thought to keep the Yank always ahead spurs on the workmen

**James L. White Dies of Influenza**

INDIANAPOLIS, Oct. 14—James L. White, assistant general manager and assistant to the president of the Cole Motor Car Co. died suddenly Oct. 10 from Spanish influenza. He had been associated with the Cole organization for many years, going there from the Northway Motor & Manufacturing Co.

J. E. Baum, of the factory service department, Nash Motors Co., Kenosha, has accepted the position of service manager of the Philadelphia Nash Motors Co. and assumed his new duties in Philadelphia on Oct. 10.

A. W. Dietzel, for several years superintendent of the Waukesha Motor Co., Waukesha, has resigned to accept the position of works manager of the I. B. Rowell Co., Waukesha, manufacturer of Ford starters, tractor parts and farm implements.

Donald R. Black, formerly chief draftsman of the L-W-F Engineering Co., is now in the Air Service, U. S. A., having been inducted by his request. He is assigned to Langley Field, Hampton, Va.

H. L. Hall has been appointed manager of the Chicago branch of the Swinehart Tire & Rubber Co.. The Central Western territory is controlled by this branch.

E. H. Geyer has been appointed general sales manager of the Hercules Motor & Mfg. Co., Canton, O. He has been associated for a number of years with the Byrne-Kingston Co. and Kokomo Electric Co., Kokomo.

Charles M. Smith, formerly affiliated with the Detroit Steel Castings Co. and the Michigan Steel Castings Co., Detroit, has been appointed superintendent of the foundry operated by the Nelson Bronze Co., Saginaw, Mich.

Frank M. Taylor has been appointed efficiency engineer of the Russel Motor Axle Co., Detroit.

**To Make Removable Body Truck**

NEW YORK, Oct. 14—A company is in process of formation for the manufacture of a new type of motor truck and removable body with which it is hoped to solve many of the short haul problems of the railroads. The plan, in brief, is to produce wheeled bodies which may be carried intact by the railroads on flat cars and shifted from these cars at the end of the run direct to motor truck chassis. The cars would then be delivered by the motor truck to the consignee, who would draw them off the truck chassis and move them into position for unloading on their own wheels. Both the truck chassis and the bodies are the invention of Jos. C. Bonner, who heads a syndicate which shortly is to be converted into a manufacturing company.

## Men of the Industry

### *Changes in Personnel and Position*

**Graham Heads "Exiles"**

WASHINGTON, Oct. 15—George M. Graham, chairman of the Motor Truck Committee of the N. A. C. C., has been elected president of a new association styled "The Exiles," in which membership is limited to men of the motor car industry who have spent two months or more in Washington since the war began. Other officers are: Vice-president, Alfred Reeves; secretary, Harry W. Perry; Automotive Products Section, War Industries Board.

**Wolverine Tractor Elects Directors**

SAGINAW, MICH., Oct. 14—The Wolverine Tractor Co. has elected the following board of directors: W. J. Wickes, Arnold Boutel and W. E. Laur of Saginaw; C. A. Bigelow of Bay City; W. E. Wood, W. G. Wagenhals and W. F. Austin of Detroit. The company has been capitalized for \$300,000, of which \$175,000 has been subscribed.

**Steel Products Builds Shop Addition**

DETROIT, Oct. 14—The Steel Products Co. has taken out a permit for a one-story machine shop addition, 89 by 123, at 2177 East Sixty-fifth Street. The estimated cost of the job is \$30,000.

**Grand Rapids Brass Enlarges**

GRAND RAPIDS, MICH., Oct. 14—The Grand Rapids Brass Co. will erect at once an addition to its factory of three stories and basement, the building to be completed before Jan. 1.

**Supplies and Accounts Contracts**

WASHINGTON, Oct. 12—The Bureau of Supplies and Accounts of the Navy Department has placed contracts as follows:

Ford Motor Co., Detroit, ambulances.  
Willys-Overland Co., Toledo, blocks.  
Livermore Mills Co., Livermore, N. H., airplane spruce.  
Curtiss A. & M. Corp., Buffalo, N. Y., HS-2 shells.

**Bureau of Supplies Orders**

WASHINGTON, Oct. 12—The following orders were placed by the Bureau of Supplies and Accounts of the Navy Department:

Jamestown Propeller Co., Jamestown, N. Y., propellers.  
Hendeen Mfg. Co., Springfield, motorcycles.  
Harley-Davidson Motor Co., Milwaukee, motorcycles.  
Federal Motor Truck Co., Detroit, motor trucks.

**Fenner Appointed Assistant to Hanch**

WASHINGTON, Oct. 10—David C. Fenner, member of the Highways Transport Committee of the New York State Council of Defense, has been appointed as assistant to C. C. Hanch, Chief of the Automotive Products Section of the War Industries Board.

Albert W. Russell, formerly president of the Russel Motor Axle Co., and treasurer of the Russel Wheel & Foundry Co., Detroit, has been appointed a member of the War Credits Board to fill a vacancy caused by the resignation of F. P. Neal.

E. B. Foote, who has for some time been connected with the sales department of the Jaxon Steel Products Co., Jackson, Mich., has been placed in charge of the newly created wheel division of that company, with headquarters in Detroit, for the marketing of the Jaxon steel wheel.

Lee Anderson, vice-president and sales manager of the Hupp Motor Car Corp., Detroit, has taken charge of the publicity and advertising work of the Aircraft Production Bureau in Detroit. Newspaper advertisements, a house organ for employees and feature posters are among the means which he will use to stimulate increased production.

C. E. Morton, formerly Pacific Coast district manager for Packard, has been appointed manager of the Packard overseas division.

Thomas A. Russell, for 2½ years chief engineer of the Tractor Bearings Division of the Hyatt Roller Bearing Co., Detroit, and J. E. Martin, for 2 years dynamometer expert of the same division, were recently commissioned lieutenants.

V. C. Fuller has been appointed special traveling representative of the Bearings Service Co., Detroit, with headquarters at the main office.

**Motor Truck Sales Managers to Meet**

CLEVELAND, Oct. 14—The first regular meeting of the Association of Sales Managers of the Motor Truck Industry will be held in this city, Oct. 18, for the purpose of electing a board of directors and executive officers. Different points regarding the sale of motor trucks, their use, the possibility of trailers and the importance of good roads will be discussed.

**New International Steel Plant**

MILWAUKEE, Oct. 14—The International Steel Products Co., manufacturing gas engine silencers and other accessories and parts of pressed sheet steel, has broken ground for its new and permanent works in Hartford, Wis., the first unit of which will cost about \$30,000.

### General Motors to Make Frigerators to Be Marketed by Car Dealers

DETROIT, Oct. 12—W. C. Durant has bought the equipment and the rights of the Guardian Frigerator Co., Detroit, thereby bringing the General Motors Co. into the ranks of general utilities manufacturers. The entire Plant 5 of the Cadillac will be utilized in the manufacture of frigerators. The new company will be styled The Frigidaire Co.

The frigerator is a large insulated box in which food is kept at a low temperature generated and controlled by means of an electric motor.

The Guardian Co. had been in business for 2 years. The inventor of the machine and founder of the company, A. W. Mellows, will retain an interest in the new company. J. W. Murray of the J. W. Murray Manufacturing Co. becomes a stockholder. The officers of the new company have not been elected.

The product manufactured, which is more than a mere ice box or refrigerator, will be marketed through the General Motors dealers and distributors, thus filling in for them to a large degree the gap which has been caused by the reduction of passenger car production.

The frigerators will be sold to dealers on the same basis as cars with a slightly better percentage of profit. There are two models—one sells for \$350, the other for \$365—and the profit averages 25 per cent. The machines will take up very little space in a dealer's showroom and no accessories need be carried in connection with the proposition.

Within 30 days it is planned to have agencies established in Washington, Atlanta, Buffalo, New York, Pittsburgh, Philadelphia, Cincinnati and Dayton. Before Jan. 1, 1919, every General Motors agency will represent this company.

### Supreme to Erect Plant

CLEVELAND, Oct. 15—The Supreme Motors Corp., Warren, Ohio, has completed arrangements for the erection and equipment of a plant in which it will produce a complete line of engines. For the present, however, the company will confine its operations to war work. The officers of the company are: President, A. W. Green, Windsor, Ohio; vice-president and general manager, C. H. Davies, Warren, Ohio; secretary, C. F. Erickson, Ashtabula, Ohio; treasurer, C. N. Mitchell, Cleveland.

### More Room for McCord

DETROIT, Oct. 14—The McCord Mfg. Co., has let the general contract on a three-story addition to its factory at Jefferson Avenue and Connors Creek.

### Hospital of Milwaukee Ford Plant

MILWAUKEE, Oct. 14—The Milwaukee assembling plant of the Ford Motor Co., formerly serving the Wisconsin and Upper Michigan territory, has been requisitioned by the Government and will be converted immediately into a hospital of 1000 beds, with full equipment of surgical laboratories, operating rooms,

## Current News of Factories

*Notes of New Plants—Old Ones Enlarged*

etc. In recent months the plant has been used entirely to supply parts to Ford dealers in this territory, the assembling of cars having been discontinued in March.

### Zenith Carbureter Enlarges

DETROIT, Oct. 14—The Zenith Carbureter Co. is erecting a new four-story addition, 40 x 64, to its factory at the foot of Hart Avenue. The new building will cost about \$75,000. The ground floor will be ready for occupancy after Nov. 1, and the balance after Dec. 1.

### Consolidated Mfg. Co. Operates 80 Per Cent on War Work

TOLEDO, Oct. 12—The Consolidated Mfg. Co. is now about 80 per cent on war work, which consists of tubing, stampings and drop forgings for everything from motorcycle side cars for the Italian government to airplane and ship forgings for the aircraft and shipping boards. The tubing division of the plant is making 100,000 tubular die handles, to be used on work of the Emergency Fleet Corp. The company formerly manufactured motorcycles, but the facilities of this branch of manufacture have been turned to the bicycle industry. The company is averaging 1500 bicycles a week.

### Continental Declares Another Dividend

DETROIT, Oct. 10—The Continental Motors Corp. has declared a dividend of 1½ per cent, payable Oct. 30, to holders of common stock of record Oct. 21. Books of the company will close at the end of business, Oct. 21, and will re-open Oct. 31. The dividend will make a total of 6 per cent the corporation has paid to owners of its common stock during the calendar year. The regular quarterly dividend of 1¼ per cent is payable Oct. 15 to owners of preferred stock of record Oct. 5. It is understood that the plants of the Continental Corporation will be running on a 100 per cent war order basis shortly before Jan. 1. The change from private to government work is being effected on a gradual basis and has been under way for some time past.

### Declare Dividends

Pyrene Mfg. Co., quarterly dividend of 2½ per cent on common.

Packard Motor Car Co., Detroit, 4 per cent on common, payable Oct. 31 to holders of record, Oct. 15.

### Kahlenberg Adds to Buildings

TWO RIVERS, WIS., Oct. 14—The Kahlenberg Bros. Co., Two Rivers, Wis., maker of marine and stationary oil engines, has commenced construction work on a large new assembling, testing and shipping building. The space released by this addition to the facilities will be devoted to manufacturing. The new building will be equipped with a large electric traveling crane and the most modern testing equipment and accessories.

### More Room for Langstadt-Meyer

APPLETON, WIS., Oct. 14—The Langstadt-Meyer Mfg. Co., manufacturer of farm lighting systems and direct-connected generating units for other purposes, is enlarging its capacity by taking over the building heretofore occupied by the Appleton Motor Car Co. as a salesroom, service station and public garage. The entire building will be converted into a machine shop.

### Oneida to Build Trailers

MILWAUKEE, WIS., Oct. 14—The Oneida Motor Truck Co., Green Bay, Wis., is reported to have been granted a large contract to build trailers to be used for mobile army kitchens by the American Expeditionary Forces.

### Kissel Adding a Building

HARTFORD, WIS., Oct. 14—The Kissel Motor Car Co., which is devoting practically its entire facilities to the production of Four Wheel Drive trucks for the Government, has awarded contracts for the erection of a one-story warehouse building, 50 x 260 ft.

### Twenty-five Houses for Foundry Workers

BUCYRUS, OHIO, Oct. 12—The Ohio Steel Foundry and Carroll Foundry & Machine Co. have let a contract to the Bucyrus Builders Co. for the erection of twenty-five moderately priced houses, valued at from \$1,800 to \$2,000 for employees.

### Another Extension for Falls

MILWAUKEE, Oct. 14—Another large addition to the plant of the Falls Motors Corp., Sheboygan Falls, Wis., will be erected immediately. It will consist of a one-story shop addition, 120 x 275, and is the fourth extension made within a year's time. The company is devoting 100 per cent of its facilities to the manufacture of engines for Government trucks and other army purposes.

### Detroit Concerns Expanding

DETROIT, Oct. 12—The Detroit Lubricator Co. has been given a building permit to erect a one-story shipping room, 104 by 120, to cost \$25,000.

The Packard Motor Car Co. has obtained a permit for an addition to its plant to cost \$30,000.

The American Car & Foundry Co. will build a two-story factory addition, 33 by 120, to cost \$20,000.

**Tractor Development in Iowa***(Continued from page 665)*

far has been able to deliver only very few machines owing to inability to get needed machine tools and other equipment. The worm gear used is manufactured for the concern by the Cleveland Worm & Gear Co. This tractor has a  $4\frac{1}{4} \times 5\frac{1}{2}$  in. four cylinder engine, and the present price is \$1,685. Some years ago William Galloway took over the old Maytag automobile plant, which is directly adjacent to its own implement plant, and this is being converted into a tractor factory.

The fourth Iowa manufacturer of farm tractors is the Dart, which has just about completed its development work and is ready to begin production. The Dart has long been known as a manufacturer of motor trucks, having for some years produced a high-wheel motor delivery wagon and more recently heavier trucks of conventional design. The firm owns a manufacturing plant of modest dimensions and will continue the manufacture of trucks. The eastern agency for the new Dart Blue J tractor has been taken over by the Maxim Munitions Corp. and the tractor has been brought prominently to public attention by the activities of this concern. The Dart tractor is the work of W. H. Johnson of the company, who has acted in a consulting capacity to other tractor firms in the past. The machine is of clean-cut design throughout.

**Leader Becomes Rex**

Des Moines also has its tractor factory in the Leader, which in 1916 took over the business of the Ohio, which was started in 1901 or 1902 and manufactured about 850 all told during its existence. Owing to the use of the name Leader by another tractor company, the Des Moines concern has chosen the name Rex for its new model, which will shortly be put in production. This is a 3-plow, 12-25-hp. tractor, weighing about 5500 lb. and using kerosene as fuel. It is fitted with a Waukesha engine  $4\frac{1}{4}$  by  $5\frac{1}{4}$ , equipped with a Kingston carbureter, Eisemann magnet with impulse starter and Perfex radiator. The fuel tank holds 20 gal. of kerosene and 5 gal. of gasoline. S K F ball bearings are used in the gearbox. The engine sets crosswise of the frame and the drive is through spur gears exclusively. A Bierman clutch is used. Two forward speeds are obtained through the sliding type gearset of  $2\frac{1}{2}$  and 4 m.p.h. respectively. Sliding pinions on an extension of the clutch shaft mesh with a double gear on the differential shaft, and thence the drive is by bull pinions and gears to the rear wheels. The rear axle, which is  $2\frac{1}{2}$  in. in diameter, turns in bearings on the axle housing.

The rear wheels are 60 x 10 in. and the front wheels 46 x 4 in. The front axle is built up and is provided with automobile type steering knuckles. The frame is made of 7-in.  $12\frac{1}{4}$ -lb. channels and is very narrow in front where it is pivoted to the front axle, this feature, of course, being designed to permit of turning the tractor in a short radius. Steering is

effected through the intermediary of screw and nut steering gear, by means of a nearly horizontal shaft, to the rear end of which is secured the steering hand wheel. It is planned to provide extensions for the steering shaft and also for the other control members, so that the tractor can be operated from the seat of an implement drawn by it, such as a binder.

**Air Cleaners Analyzed and Compared***(Continued from page 680)*

of water containing dust are thrown out of the air while passing through the inner cleaner and drop back into the water reservoir again. This also accounts for the low water consumption.

Except at the instant of starting, the frictional resistance of this water cleaner is no greater than that of an equivalent one of the dry type because after once started it requires but little force to keep the body of water revolving.

**Air Cleaner Types**

The fourth type of air cleaner and the most widely used works on the centrifugal or gravity principle. Figs. 7 and 8 are examples of this type of cleaner. Fig. 8 was the first successful centrifugal or gravity cleaner on the market and is used on 75 per cent of the different makes of tractors which use air cleaners. It has been so widely used during the past 3 years as to require little explanation. The air is drawn by the motor suction through the openings in the sides of the cleaner into the spiral tubes. These spiral tubes have a downward pitch which gives the dust laden air a whirl, so that centrifugal action and gravity throws the dust out of the air under the cone and into the container below, while the clean air passes upward through the top and into the carbureter.

Fig. 7 shows a centrifugal cleaner of the same type as Fig. 8, differing only in outward appearance and size. The principle and action are identical and the construction nearly so.

There are several other forms of the four types of cleaner, but the ones shown and described in this paper are representative and serve to show the principles and design involved.

**Electric Dynamometers for Aircraft Engine Tests***(Continued from page 677)*

neto of the engine in case of tripping of the main circuit breaker, and to this is frequently added an attachment for shorting the engine ignition in the event of overspeed.

For the measurement of speed an indicating tachometer is regularly provided, either of the electric type or of the same type as is used in the airplanes themselves. It is customary also to have a speed counter for accurate measurement of the revolutions.

A recent application of the electric dynamometer is for the making of efficiency and endurance tests on propellers. The dynamometer is used as a driving

motor and the propeller is mounted upon a sliding shaft coupled to the dynamometer in such a manner that not only is the torque required to drive the propeller measured, but the thrust or reaction is also indicated. This arrangement is proving of great value in making overspeed tests on propellers.

Electric dynamometer testing of airplane engines is coming into very general use in all of the different departments of the Government in which engine tests are made, and with the leading engine manufacturers.

One of the most noteworthy installations of electric dynamometers is in one of the plants of the Willys-Overland Co., where engines of the training type have been produced. This plant has put over 6000 engines through the electric test and was the first plant in the country to reach a production of fifty airplane engines a day.

**Tractor Makers Protest Curtailment***(Continued from page 659)*

- W. S. Franklin, Jr., secretary Parrett Tractor Co., Chicago, Ill.
- R. F. Florian, general manager Square Turn Tractor Co., Norfolk, Neb.
- Merritt J. Osborn, general manager Nilson Tractor Co., Minneapolis, Minn.
- S. G. Miller, president Belt-Rail Tractor Co., St. Paul, Minn.
- H. C. Berry, engineer U. S. Tractor & Machinery Co., Chicago, Ill.
- J. B. Foote, president Foote Bros. Gear & Machine Co., Chicago, Ill.
- J. C. Westmont, general manager Wisconsin Farm Tractor Co., Sauk City, Wis.
- B. J. Larkin, vice-president Brewer Mosel Automobile Co., Madison, Wis.
- M. D. Herron, sales director Dart Truck & Tractor Corp., Waterloo, Iowa.
- P. Morris, Illinois Tractor Co., Bloomington, Ill.
- M. B. Falvey, Kokomo Electric Co., Kokomo, Ind.
- A. C. Bennett, Wilcox-Bennett Carburetor Co., Minneapolis, Minn.
- D. V. Kennedy, sales engineer Perfex Radiator Co., Racine, Wis.
- George D. Bailey, G. D. Bailey Co., Chicago, Ill.
- Henry Farrington, Agrimotor, Chicago, Ill.

**Implement Dealers Losing Tractor Sales***(Continued from page 684)*

once every year. One session is a joint meeting. Each organization sends to the other in advance of the joint conference a list of subjects which it appears desirable to discuss in order that sales managers and dealers may reach accord, if possible, upon trade policies which affect both. This joint conference is highly regarded by both. *What takes place at that conference is likely to make implement history.* There is a frank interchange of opinion. Manufacturers and dealers, through their accredited representatives, meet face to face and let the bars down. *Policies momentous to the implement trade have been determined upon at past conferences; policies equally momentous will be determined at future conferences.*

That was the stage upon which the drama of last week was played.

Patent leveling, 25c. per 100 lb.		
Resquaring, 5 per cent of gage price after quality, finish and size extras have been added.		
Seconds 10 per cent less than the invoice Pittsburgh price for corresponding primes.		

## Knobloch in Ordnance Department

CLEVELAND, Oct. 14—A. F. Knobloch, vice-president and works manager of the Cleveland Tractor Co., Cleveland, has been appointed assistant to L. J. Horowitz in the Ordnance Department at Washington. In that capacity he will represent Mr. Horowitz in matters having to do with the practical, manufacturing and technical details in providing the fighting tanks required in Europe.

## Wheel Makers Convene

DETROIT, Oct. 16—Representatives of 24 manufacturers of wheels attended the third meeting of the Automotive Wheel Association held here yesterday. How the manufacturers can better assist the Government and efforts to standardize the wheel industry were the principal subjects discussed. The next meeting will be held at Chicago Dec. 9.

## Complete Detroit-Toledo Road

DETROIT, Oct. 16—The last 14 miles of paved highway between Detroit and Toledo were formally opened to traffic yesterday after appropriate dedicatory ceremonies had been held. A Govern-

ment train of twelve army trucks was the first to traverse the new road, which is the most important link of state highways in Michigan, as it is the gateway to the seaboard. The newly completed section of road was in course of construction since 1915, and from time to time new pieces were added until the entire 14 miles were completed. Eleven miles were built during this year and 3 miles since 1915. The cost of the project was approximately \$600,000.

## Federal Withdraws 3½-Ton Model

DETROIT, Oct. 16—The Federal Motor Truck Co. has withdrawn from the commercial market its 3½-ton truck. The move has been necessitated by the heavy demand by the Government for vehicle of this type.

## American Bronze Makes Changes

BERWYN, PA., Oct. 14—The American Bronze Co. has made a number of changes in its organization. Matthew C. Dittman, vice-president and treasurer, has been appointed general manager, and C. H. Baker, formerly auditor of the Timken Roller Bearing Co., Canton, will be his assistant. E. G. Anderson, sales

manager, has been appointed advertising manager.

## Curtail Road Making Machinery and Parts

WASHINGTON, Oct. 10—Road making machinery and parts cannot be manufactured in any quantities for the 6 months beginning Oct. 1, 1918, except:

- Repair parts.
- For work for railroads and other public utilities.
- For roads repaired by the United States Government, the several states, counties and municipalities.
- For new construction by the United States Government either directly or indirectly.

This curtailment is by the order of the War Industries Board. Briefly, it means that no road making machinery will be manufactured for the construction of new highways except where such construction is either directly or indirectly for the Government. Parts for the repair of road making machinery can be secured however, where the machinery is to be used in the repair of roads and highways either for the Government or for state, county or municipal order.

## Contracts Placed

WASHINGTON, Oct. 14—The following orders were placed by the Bureau of Aircraft Production:

Wright-Martin Aircraft Corp., New Brunswick, engine spares.  
Spranger Wire Wheel Co., Detroit, spares for planes.  
Howell & Lesser, San Francisco, Cal., spares for planes.  
Budd Wheel Corp., Philadelphia, spares for planes.  
Marlin-Rockwell Corp., New York, radiators.  
The Acklin Stamping Co., Toledo, Ohio, spares for Handley-Page.  
B. F. Goodrich Co., Akron, tires and tubes.  
Willys-Overland Co., Toledo, nuts.  
Light Mfg. & Foundry Co., Pottstown, Pa., lower crank cases.
